Novel use of a cardiac septal occluder to treat a chronic recalcitrant bariatric fistula after Roux-en-Y gastric bypass

Although considered the gold standard for the treatment of obesity, bariatric surgeries are not free of complications. Fistulas occur after Roux-en-Y gastric bypass (RYGB) and sleeve gastrectomy in up to 8.3% and 7% of patients, respectively [1, 2]. We describe the first report of the off-label use of the cardiac septal occluder (AMPLATZER Septal Occluder; Abbott, St. Paul, Minnesota, USA) for the treatment of a chronic bariatric fistula (▶ Video 1).

A 33-year-old man with grade II obesity underwent RYGB. After 1 week, the patient remained asymptomatic at the 3-month follow-up. The cardiac septal occluder device appears to be effective and safe in the treatment of chronic bariatric fistulas. It seems to be an option mainly after conventional therapies have failed.

Emergency surgery was indicated, a peri-gastric collection associated with a gastric pouch leak was confirmed, and placement of two abdominal drains was performed, followed by admission to the intensive care unit. After 25 days, the drain output was 300 mL/day, and an upper endoscopy showed a 20-mm leak in the gastric pouch in the topography of the superior staple line, just below the esophagogastric junction (▶ Fig. 2). An esophageal fully covered metal stent (Hanaro, 16 cm × 22 mm; Micro Tech Co. Ltd., Anseong-Si, South Korea) was placed (▶ Fig. 3). The stent was fixed with the Shin technique to avoid migration [3]. After the stent placement, the drain output decreased to 30 mL/day. The stent was removed 4 weeks later because of patient intolerance. During the endoscopy, a chronic fistula (15 mm) with the external drain tube inside the orifice was observed. The drain was removed under direct endoscopic vision, until the endoscope was advanced to...
the skin. The fistula tract was noted to be fully epithelialized.

As this chronic fistula remained unresponsive, placement of a cardiac septal occluder was performed (▶Video 1, ▶Fig. 4) [4, 5].

After 15 days, the cutaneous ostium was closed completely (▶Fig. 5). The patient remained asymptomatic at the 3-month follow-up.
