Endoscopic ultrasound-guided gallbladder drainage as a strategy to overcome shortage of operating rooms and intensive care unit beds during Covid-19 crisis

The Covid-19 outbreak has induced dramatic changes to health care in Italy. Restrictions to intensive care units (ICU) and operating rooms to care for Covid-19 patients has limited the facilities available for infection-free patients [1, 2]. We report on a patient with sepsis due to acute cholecystitis who was managed entirely outside the operating room and ICU.

An 80-year-old woman who had been admitted to a rehabilitation institute 20 days earlier following a spinal injury, developed sepsis. Liver enzymes (aspartate aminotransferase 89 U/L), white blood cells (27 000 /mm³), bilirubin (2.9 mg/dL), and C-reactive protein (37.2 mg/dL) were markedly elevated. Her condition worsened overnight and she was referred to hospital. Computed tomography showed marked dilation of the gallbladder with thickened walls and multiple radio-opaque stones. Additionally, complete collapse of the left lung and findings suspicious for Covid-related pneumonia were reported (▶ Fig. 1). As ICU was unavailable, and following multidisciplinary evaluation, she was moved to the endoscopy suite for drainage. Pending Covid-19 results, she was managed as a positive case as a precaution (i.e. negative-pressure room, personal protective equipment) (▶ Fig. 2).

Endoscopic ultrasound-guided gallbladder drainage (EUS-GBD) was preferred over percutaneous drainage to allow definitive treatment and, potentially, rapid discharge from hospital [3–5]. EUS-GBD was achieved by placement of a 10-mm electrocautery-enhanced lumen-apposing metal stent (▶ Fig. 3, ▶ Fig. 4, ▶ Video 1). The procedure lasted 20 minutes and was conducted under deep sedation. The patient experienced prompt reduction of abdominal pain and remained afebrile. No complications developed and she was discharged 4 hours later. She resumed oral feeding the fol-
The following day, and biochemical abnormalities started to return to normal.

EUS-GBD is established for acute cholecystitis in high-risk surgical patients. During the Covid-19 crisis, indications for this minimally invasive treatment may expand in order to avoid more resource-consuming interventions such as surgery and intensive care admissions.
