

Postsurgical bile duct disruption: Digital single-operator cholangioscopy-assisted recanalization

► **Fig. 1** Computed tomography scan, axial section, showing subhepatic collections compatible with bilomas.

► **Fig. 2** Fluoroscopy during endoscopic retrograde cholangiopancreatography showing common bile duct stenosis and biliary leak. The intrahepatic bile duct shows no opacification. Second guide in the main pancreatic duct (double-guide-wire technique).

► **Fig. 3** Fluoroscopy during percutaneous transhepatic cholangiography showing dilated intrahepatic bile ducts. The extrahepatic bile duct shows no opacification.

Treatment of postsurgical biliary leaks is complex and depends on their severity. Endoscopic treatment is usually preferred, but it can be difficult in cases of complete duct transection. However, most patients with a biliary leak are septic and are therefore not eligible for a surgical approach [1, 2, 3].

We present the case of a 59-year-old patient who developed jaundice and fever 10 days after a hepatic metastasectomy (segments II and IVa). A computed tomography (CT) scan showed a 14-cm perihepatic collection, compatible with an infected biloma (► **Fig. 1**).

Endoscopic retrograde cholangiopancreatography (ERCP) demonstrated a stenosis of the proximal common bile duct (CBD), a biliary leak, and no opacification of the intrahepatic bile duct (► **Fig. 2**). A sphincterotomy was performed and two transpapillary nasobiliary drainage catheters (7 F and 8.5 F) were placed. The biloma was percutaneously drained. Cannulation of the CBD 1 month later was not successful using a radiological approach with percutaneous transhepatic cholangiography (► **Fig. 3**).

A combined percutaneous and endoscopic treatment was planned (► **Fig. 4**, ► **Video 1**). The stenosis of the CBD was dilated and a cholangioscope was introduced in the collection via ERCP. A guide was advanced via percutaneous transhepatic cholangiography, captured within the collection with direct vision using a snare, and advanced to the duodenum. With maintained endoscopic traction of the guide, a percutaneous 8.5 F plastic catheter was inserted, with the proximal fenestrated portion in the intrahepatic bile duct and the distal fenestrated portion in the CBD. Finally, a plastic biliary stent (9 cm/10 F) was placed. Fluoroscopic control images showed continuation between the intrahepatic and common bile duct (► **Fig. 5**). The plastic catheter was exchanged for a biodegradable biliary stent 6 weeks later. Final recanalization was achieved.

► **Fig. 4** Combined-approach fluoroscopy. The intraductal cholangioscope captures a percutaneous transhepatic guide within the biloma.

► **Fig. 5** Post-treatment fluoroscopic control showing continuity between the intrahepatic and extrahepatic bile ducts and resolution of the biliary leak.

Biodegradable biliary stents show good technical and clinical success in biliary fistula treatment [4]. In this case, the cholangioscope was the key element for the described rendezvous, illustrating the diagnostic and therapeutic advantages of direct visualization of the biliary duct [5]. A multidisciplinary approach is crucial for a good clinical outcome in these challenging cases [2, 3].

Video 1 Spyglass cholangioscopy-assisted rendezvous in postsurgical bile duct disruption. We combined a radiologic approach via percutaneous transhepatic cholangiography with an endoscopic approach via endoscopic retrograde cholangiopancreatography and intraductal cholangioscopy, achieving reconnection of the bile ducts.
