Unusual endoscopic findings in an immunosuppressed patient

Immunosuppressed patients are susceptible to infections by opportunistic agents such as *Leishmania* that could cause visceral leishmaniasis with gastrointestinal involvement in up to 10% of cases. We report a 41-year-old man with human immunodeficiency virus (HIV) infection stage C3 with CD4 lymphocytes 81/mm³, 4,070 leukocytes (47.2% lymphocytes, 0.0% eosinophils, rest of differential normal) treated with antiretroviral therapy (dolutegravir/abacavir/lamivudine) with good adherence. He also reported mesangiocapillary glomerulonephritis type-1, hepatocutaneous porphyria, and a 7-year history of recurrent visceral leishmaniasis treated with liposomal amphotericin B as secondary prophylaxis. Esophagogastroduodenoscopy and colonoscopy indicated for chronic diarrhea and anemia performed 5 years ago displayed antral erythema, mild nodular appearance in the duodenal mucosa, and normal colonic mucosa. Gastric, duodenal, and colonic biopsies revealed *Leishmania spp* despite treatment with liposomal amphotericin B.

A video capsule endoscopy (VCE) was now indicated for persistent diarrhea. Enteropathy with atrophic and patchy, marked edema of the villus, and whitish nodularity with a “river bedrock” appearance (▶Fig. 1–3) in the duodenum and jejunum were identified (▶Video 1). Further gastric and duodenal biopsies showed an accumulation of macrophages in the lamina propria of the mucosa with intracytoplasmatic *Leishmania spp* (▶Fig. 4). Treatment with meglumine antimoniate was initiated owing to previous failure with liposomal amphotericin B, without response.

Some cases of visceral leishmaniasis showing non-specific findings (atrophy, edema, and whitish nodular mucosa) on esophagogastroduodenoscopy have been reported [1,2], with the mucosa appearing normal in up of 45% of cases [3,4]. There is only one case reporting

▶Video 1 Unusual endoscopic findings in an immunosuppressed patient.

▶Fig. 1 Marked edema of villi and whitish nodularity in the proximal duodenum.

▶Fig. 2 Isolated erythematous nodules in the jejunum (arrows).

▶Fig. 3 Atrophic and patchy duodenal pattern with whitish nodularity observed on esophagogastroduodenoscopy.

▶Fig. 4 Accumulation of macrophages in the lamina propria of the mucosa with amastigotes of *Leishmania protozoa* in their cytoplasm; hematoxylin and eosin, ×40.
VCE findings of visceral leishmaniasis in an immunocompromised patient with a diffuse intestinal atrophic pattern [5]. We observed a similar enteropathy, although in a patchy distribution, on VCE and esophagogastroduodenoscopy. Atrophic enteropathy displayed as a “river bedrock” appearance would be a possible sign of an advanced stage of life-threatening visceral leishmaniasis. VCE may provide useful information on diagnoses, extension, and severity of gastrointestinal lesions in patients with severe immunosuppression and gastrointestinal symptoms.
