Endoscopic submucosal dissection (ESD) is the technique of choice for the resection of superficial colorectal lesions larger than 20mm [1], but the procedure can be technically challenging in some situations. If a lesion involves a diverticulum, there is fear of a higher risk of perforation due to the lack of muscle layer. However, ESD has recently been described as safe and effective in this particular case [2]. Use of a clip and rubber band (counter-traction technique [3]) can help to achieve a satisfying resection with higher technical comfort. This technique has been proved to be effective and safe for resection of neoplastic lesions involving the appendiceal orifice [4]. However, few data are available for lesions involving a diverticulum [5].

We report the case of a 40 × 30 mm non-granular laterally spreading tumor (NG-LST) deeply invading a colonic diverticulum (Type 3 LST) (Fig. 1), which was resected with ESD using the counter-traction technique (Video 1). After submucosal injection around the diverticulum, complete circumferential incision and deep trimming were performed. The first clip grasping a rubber band was fixed at one side of the lesion and a second clip grasping the same rubber band was fixed at the opposite colonic wall (Fig. 2). This counter-traction technique allowed better exposition of the submucosa area under the diverticulum, thus strongly facilitating an en bloc resection (Fig. 3). The ulcer floor of the diverticulum was closed by two clips at the end of the procedure to prevent delayed perforation [2]. The patient was discharged the following day without any adverse events. The histopathology report showed an adenoma with high grade dysplasia and a complete en bloc resection (R0).

Endoscopic submucosal dissection of a laterally spreading tumor involving a colonic diverticulum using the counter-traction technique
