Endoscopic closure of endoscopic submucosal dissection (ESD)-induced gastric defects using an endoloop and endoclips may prevent delayed bleeding in patients who are receiving anticoagulants [1]. Several technical variations of the endoloop and endoclips technique have been described, some of which also use single-channel endoscopes [2], which are in widespread use. Their successful application is however being undermined by a number of pitfalls, both procedure-related (e.g., respiratory fluctuations, poor endoloop device maneuverability when kept outside the endoscope) and instrument-related (e.g., difficulty grasping the tail or stem of the device) [3]. Herein, we illustrate a modification of the endoloop and endoclips technique, inspired by the “loop 9” method [4], that can be applied as a less cumbersome yet effective alternative to similar procedures.

The modified procedure, which we have termed “bead, loop, and clips (BLC) closure” was applied post-ESD for an early gastric cancer in a 68-year-old man who was receiving low dose aspirin. Initially, the stem of an endoloop is manually elongated so that it can be passed through a 6-mm bead. A 3–0 nylon thread is then tied onto the tail end of the endoloop, distally to the bead (▶ Fig. 1a). After the successful completion of the ESD, the “beaded” endoloop is passed through an overtube into the esophagus and stomach, and is anchored onto the edge of the mucosal defect using a reopenable endoclip. Additional endoclips are used to fix the endoloop to the margins of the defect.

A small caliber disposable biopsy forceps (Radial Jaw 4P, Boston Scientific, Boston, Massachusetts, USA) fitted into the outer...
sheath of a disposable endoloop device (HX-400U-30; Olympus, Tokyo, Japan) (Fig. 1b) is then inserted through the single-channel endoscope to grasp the endoloop tail and pull it into the sheath. Throughout this process, the bead serves as an “anchor” or “keeper” that permits endoloop tightening and subsequent defect closure (Fig. 2). Finally, the bead can be removed using biopsy forceps. The entire procedure is shown in Fig. 3 and Video 1.

The procedure was uneventful and on endoscopy performed on the fourth day post-ESD, the defect remained closed (Fig. 4).
