Tunnel creation method in endoscopic necrosectomy for walled-off pancreatic necrosis

Walled-off pancreatic necrosis (WON) is one of the most severe complications of acute pancreatitis, and endoscopic necrosectomy may be necessary to treat this complication [1,2]. When treating a large WON, if only the shallow section is treated, the route to the deepest section may be closed, leaving a space wherein endoscopic necrosectomy cannot be performed [3]. It is important to identify the deepest section of the WON and secure the route by stent placement. Herein, we propose a novel “tunnel creation method” (TCM), which is an endoscopic bougie under fluoroscopy along the stent deployed at the deepest part of the WON that provides a wide working space and a route to the deepest part (Fig. 1).

A 75-year-old man was transferred from another hospital for treatment of a large WON. Endoscopic ultrasound-guided transgastric drainage was performed using a lumen-apposing metal stent with a diameter of 15 mm (Hot AXIOS; Boston Scientific, Marlborough, Massachusetts, USA). Contrast-enhanced computed tomography 12 days after the procedure revealed that a large amount of necrotic tissue remained (Fig. 2). The left side of the WON was filled with necrotic tissue, making it difficult to secure a clear visual field during endoscopic necrosectomy. TCM was performed (Fig. 3, Fig. 4, Fig. 5, Video 1). Following this procedure, the route through which the scope passed was dilated, providing a wide working space and securing a clear visual field during endoscopic necrosectomy. The patient was discharged without any adverse events after six sessions of endoscopic necrosectomy.
It is sometimes difficult to visualize the entire WON, especially when it is large, as in this case. Using TCM, we could reach the deepest part of the WON at an early stage of treatment and visualize the whole WON, leading to more efficient treatment.
