Novel technique for treating simple hepatic cysts: endoscopic transgastric hepatic cyst deroofing

Simple hepatic cysts are common benign liver lesions which are usually asymptomatic and discovered incidentally. However, larger lesions may need surgical treatment if patients present with abdominal pain, epigastric fullness, or early satiety [1]. American Society of Gastroenterology clinical practice guidelines recommend that symptomatic simple hepatic cysts may be managed with laparoscopic deroofing rather than aspiration and sclerotherapy [2]. Natural-orifice transluminal endoscopic surgery (NOTES) has been developed as a step towards less invasive procedures [3]. With the development of digestive endoscopy, some researchers have used endoscopic ultrasound-guided fine-needle aspiration or NOTES technology for cystic fluid aspiration. Herein, we report a novel approach to smoothly achieving unroofing of simple hepatic cysts, called endoscopic transgastric hepatic cyst deroofing (ETGHCD).

A 73-year-old man complained about abdominal pain and epigastric fullness, which was significantly impacting on his daily life. Abdominal computed tomography and ultrasonography revealed an 8-cm simple cyst located in the right liver as the underlying disease. To address the issue we performed ETGHCD on the patient. During the procedure the anterior wall of the gastric antrum was perforated with a sterile colonoscope. The cyst was found at the lower edge of segment IV of the liver. After endoscopic ultrasonography reconfirmed the cyst, transparent liquid was extracted with a 23-G puncture...
needle (Boston Scientific) and sent for examination. After all fluid was extracted from the cyst, we opened the cyst wall and removed it piecemeal with a snare at the interface with the hepatic parenchyma, sealed the vessels of the cyst wall, flushed the abdominal cavity, and closed the gastric wall. The ETGHCD technique, which was applied to the large hepatic cyst located on the surface of the liver, was performed and deroofing of the cyst was achieved, thus avoiding surgery (▶Fig.1, ▶Video 1). The postoperative course was uneventful. The patient was discharged 2 days after endoscopic surgery. His symptoms resolved completely during the following 6 months.

ENDOSCOPY E-VIDEOS
https://eref.thieme.de/e-videos

Endoscopy E-Videos is an open access online section, reporting on interesting cases and new techniques in gastroenterological endoscopy. All papers include a high quality video and all contributions are freely accessible online. Processing charges apply (currently EUR 375), discounts and waivers acc. to HINARI are available.

This section has its own submission website at https://mc.manuscriptcentral.com/e-videos
