#### Abstract

We report a strategy for the stereoselective synthesis of 1,2-trans-glycosides in the absence of neighboring group participation. The present protocol for the selective glycosylation mainly relies on catalyst control rather than protecting group selection. By using this protocol, several glycosides were prepared. Zinc acetate was found to be the optimal catalyst, providing the desired 1,2-trans-glycosides from glucose- and mannose-derived glycosyl halides at room temperature instead of low-temperature conditions.

Key words glycosyl chloride, no neighboring group participation, 1,2-trans-glycosylation, zinc acetate

Biological functionality of the carbohydrate molecules is highly dependent on the nature of the glycosidic bonds. Therefore, the stereoselective synthesis of 1,2-trans-glycosidic bonds in the absence of anchimeric assistance is one of the most important and challenging reactions in carbohydrate chemistry. ${ }^{1}$ Several elegant methodologies have been developed for the synthesis of oligo- and polysaccharides with stereocontrol of the glycosidic linkages; ${ }^{2}$ however, most of the developed methodologies rely on neighboring group participation for stereoselective control of the glycosidic linkages, ${ }^{3}$ despite having certain limitations. Specifically, such protocols require the introduction of groups such as OAc, OBz, OPiv, OLev, OPicolyl, N-TCA, or N -Troc into the glycoside moiety to direct nucleophilic attack of the coupling partner. ${ }^{3 \mathrm{c}}$ However, the incorporation of such
groups is often troublesome, requiring additional steps for the regioselective introduction and removal of the participating group. In addition, this approach can limit substrate scope and often decreases overall efficiency.

Other methods that provide trans-glycosylated products in the absence of anchimeric assistance are fluorine-directed, ${ }^{4}$ and alkoxymethyl-directed ${ }^{5}$ glycosylation. However, most of these methods require several steps to synthesize orthogonally protected monomer building blocks as starting materials. Furthermore, they require excess of metal triflates to convert stable orthoester intermediates into the desired glycosides. ${ }^{6}$ Therefore, the development of catalytic stereoselective methods for 1,2-trans glycosylation is highly desirable.

Recently, reagent-controlled glycosylation has become an effective strategy for activation of sugar donors using $\mathrm{S}_{\mathrm{N}} 2$ displacement reactions with different nucleophiles. ${ }^{7}$ Most often, the activation of glycosyl chlorides requires stoichiometric amount of reagents, such as silver(I) or mercury(II) salts. ${ }^{8}$ There have been a few reports in which activation of glycosyl chlorides takes place in the absence of anchimeric assistance using $\mathrm{FeCl}_{3}{ }^{9 \mathrm{a}}$ and bis-thioureas. ${ }^{9 b}$ However, the outcome of the stereochemistry was unpredictable and provided mixtures of $\alpha$ - and $\beta$-anomers. Separation of these diastereomers is extremely challenging. Another important strategy for 1,2 -trans-glycosylation is $\mathrm{S}_{\mathrm{N}} 2$ type displacement of highly unstable in situ generated per-O-TMS glycosyl iodides with suitable nucleophile in the presence of a suitable activator. ${ }^{10}$ Other than glycosyl halides, recently Bennet et al. ${ }^{11}$ reported activation of thioglycosides using aryl(trifluoroethyl)iodonium triflimide as an activator. However, this procedure requires the use of the bulky base 2,4,6-tri-tert-butylpyrimidine (TTBP) and a multiple solvent system. Thus, development of general and catalytic methodologies to stereocontrol glycosylations without
neighboring group participation is highly desirable. The processes outlined herein rely on catalyst control rather than on neighboring group participation. As a prelude to this, we observed that the readily available and stable $\mathrm{Zn}(\mathrm{OAc})_{2}$ catalyst in the absence of base, ligand, and promotors is a useful alternative metal catalyst for the KoenigsKnorr type glycosylation at room temperature.

Optimization of the reaction parameters was explored using 2,3,4,6-tetra-O-benzyl- $\alpha$-D-glucosyl halide (1a) ${ }^{12}$ as the glycosyl donor and $n$-hexanol ( $\mathbf{2 a}$ ) as the acceptor (Table 1). Most of the classical Lewis acids $\left[\mathrm{ZnCl}_{2}, \mathrm{InCl}_{3}\right.$, $\mathrm{Cu}(\mathrm{OTf})_{2}, \mathrm{Zn}(\mathrm{OTf})_{2}$ ] failed to promote the glycosylation reaction at room temperature, while, at higher temperatures, decomposition of the glucosyl halides was observed (entries 1-4). Interestingly, diethylzinc provided the desired 1,2-trans-glycoside product in moderate yield (entry 5).

To improve the yield of the desired product 4a, we further continued our screening with $\mathrm{Zn}(\mathrm{OAc})_{2}$ in toluene, and found that 4a was obtained in moderate yield along with unwanted glucosyl acetate 5a (Table 1, entry 6). We then explored the reaction by replacing toluene with DCM. Zinc acetate successfully catalyzed Koenigs-Knorr glycosylation at room temperature in DCM, and provided the desired compound $\mathbf{4 a}$ in $75 \%$ yield with complete 1,2-trans-selectivity (entry 7). However, with increasing catalyst load, the amount of unwanted byproduct $\mathbf{5 a}$ also increased (entry 8). Anomeric $\alpha$-participating solvents such as acetonitrile ${ }^{13}$
(entry 9) did not change the selectivity, and $\beta$-participating solvents such as $\mathrm{Et}_{2} \mathrm{O}^{14}$ (entry 10) did not alter the selectivity either. Further attempts to improve yield of the desired product with $\mathrm{Pd}(\mathrm{OAc})_{2}$-catalyzed activation of the glycosyl halide was also not successful (entry 11). These observations led us to choose $\mathrm{Zn}(\mathrm{OAc})_{2}(50 \mathrm{~mol} \%)$, in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at room temperature as the optimal conditions (entry 7).

The structure and anomeric selectivity for the formation of the desired glucoside $\mathbf{4 a}$ were confirmed from ${ }^{1} \mathrm{H}$ NMR spectroscopy, where the anomeric proton (H1) appeared at $\delta=4.39 \mathrm{ppm}(\mathrm{d}, J=7.8 \mathrm{~Hz}, 1 \mathrm{H})$. The corresponding ${ }^{13} \mathrm{C}$ NMR signal for the $\beta$-isomer carbon (C1) appeared at $\delta=103.7 \mathrm{ppm} .{ }^{15 \mathrm{a}} \mathrm{A}$ very diagnostic ${ }^{13} \mathrm{C}$ signal for the $\alpha$-isomer would appear at $\delta=96.8$ (C1) ppm. ${ }^{15 \mathrm{~b}}$ We next examined the scope and generality of the optimized reagent system with a wide range of nucleophiles. Initially, we explored the utility of the protocol for the synthesis of $\beta$ glucosides. Scheme 1 lists the $\mathrm{Zn}(\mathrm{OAc})_{2}$-catalyzed glycosylation reaction between glucosyl donor 1a and various aglycone 0 -nucleophiles, including primary and secondary alcohols. Various alcohols including $n$-hexanol, geraniol, citronellol, phenyl ethanol, cholesterol, fenchol, and menthol reacted with glucosyl chloride to give the corresponding 1,2-trans-glycosides 4a-r in 60-75\% yields with complete 1,2 -trans-selectivity. It is pertinent to mention that the current glycosylation strategy was extended to acid-sensitive

Scheme $1 \mathrm{Zn}(\mathrm{OAc})_{2}$-catalyzed reaction between glucosyl chlorides and $O$-nucleophiles. Reagents and conditions: Glycosyl halide ( 1 equiv) reacted with corresponding alcohol ( 1.2 equiv) in the presence of $\mathrm{Zn}(\mathrm{OAC})_{2}$ ( $50 \mathrm{~mol} \%$ ) at room temperature.

TMS-protected alcohols such as TMS-ethanol (compound 41), and the nitrogen containing 3-azido-1-propanol also reacted smoothly to yield desired compound $4 \mathbf{m}$ (62\%).

Having obtained excellent results with glucosyl chlorides, we turned our attention to mannopyranoside chloride and mannofuranoside chloride donors (Scheme 2). ${ }^{11}$ In this case, the reaction using donors $\mathbf{1 b}$ and $\mathbf{1 c}$ gave the desired mannopyranoside glycosides 6a-c and mannofuranoside glycosides 7a-f with good yields, but the stereoselectivity was compromised. We presume that, due to the strong endo-anomeric effect in mannose derivatives, competition between $\mathrm{S}_{\mathrm{N}} 2$ and $\mathrm{S}_{\mathrm{N}} 1$ pathways leads to diastereomeric mixtures with the trans-glycosylated product as the major stereoisomer.

The scope of the reaction was further tested with various nucleophiles to yield the desired glycosides in good yields (Scheme 2). Furthermore, a gram-scale synthesis of $\beta$-allyl glucopyranoside $4 s$ was achieved using allyl alcohol and glucosyl chloride in $60 \%$ yield (Scheme 3$)^{20}$.

The mechanistic pathway for this 1,2-trans-glycosylation is not currently conclusive, although a proposed mechanism is depicted in Figure 1. The initial activation of the alcohol acceptor with $\mathrm{Zn}(\mathrm{OAc})_{2}$ produces reaction intermediate I, which coordinates with the glucosyl chloride and delivers the nucleophile from the $\beta$-face via an $S_{N} 2$ mechanism, resulting in the 1,2-trans-glycosylated product as the sole diastereomer. The catalytic cycle continues by the activation of the glycosyl chloride with intermediate II, which leaves $\mathrm{ZnCl}_{2}$ in the reaction medium that reacts further with acetic acid to reform $\mathrm{Zn}(\mathrm{OAc})_{2} \cdot{ }^{16 \mathrm{a}}$ In the case of mannopyranosides and furanosides, a mixture of diastereomers with the 1,2-trans-glycosylated product as major isomers was observed. This is probably due to the strong endo-anomeric effect operating via an $\mathrm{S}_{\mathrm{N}} 1$ mechanism. ${ }^{16 \mathrm{~b}-\mathrm{d}}$

In summary, we have developed a 1,2-trans-glycosylation protocol of glycosyl chlorides with various O-nucleophiles in the presence of $\mathrm{Zn}(\mathrm{OAc})_{2}$. The protocol described herein is efficient and furnishes the desired 1,2-trans-glycosylated products from glucopyranoside, mannopyranoside, and mannofuranoside chlorides. Mechanistic investigations as well as applications of this protocol in the synthesis of glycoconjugates are in progress.

## Synthesis of 4a-r, 6a-c, and 7a-f; General Procedure

To a stirred solution of glycosyl chloride $\mathbf{1 a - c}(83 \mathrm{mg}, 0.15 \mathrm{mmol})$ in anhydrous $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \mathrm{~mL})$ was added the requisite alcohol ( 0.18 mmol ) and $\mathrm{Zn}(\mathrm{OAc})_{2}(0.075 \mathrm{mmol})$ at room temperature, and the resulting solution was stirred at room temperature for 5 h . The reaction mixture was evaporated under reduced pressure, and the residue was purified using silica gel column chromatography (EtOAc/hexane, 2:8).
