Coronavirus disease 2019 (COVID-19) emerged as a global pandemic associated with high rates of morbidity and mortality. To face this health crisis, the government had to resort to exceptional measures to stop the spread of severe acute respiratory syndrome coronavirus 2, notably two consecutive lockdowns in 2020. This greatly impacted the health care system, including a reduction in nonurgent care activities outside of COVID-19 and a massive deployment of tools to better manage COVID-19 patients, particularly with the use of laboratory tests with diagnostic and prognostic values. In 2020, the French state health care budget recorded its highest annual deficit since its creation, at 36.8 billion euros.

Beyond the context of COVID-19, laboratory tests occupy a central place in health care. Indeed, more than 70% of clinical decisions are influenced by test results, as are around 40% of primary care consultations. Among laboratory tests, hemostasis tests are mainly used to (1) establish whether an individual is at risk of bleeding before an elective or urgent surgery or procedure, (2) monitor anticoagulant therapy, (3) diagnose specific conditions like coagulopathy and exclude venous thromboembolism (VTE) or heparin-induced thrombocytopenia (HIT).

The aim of our study was to analyze temporal trends of hemostasis tests performed in France and the impact of the COVID-19 pandemic.

We collected the number of hemostasis test reimbursements each year in France using the French national health insurance database from January 1, 2013 to December 31, 2021. This database included all reimbursed biological tests that were ordered for outpatients or hospitalized patients in private, for-profit health care facilities. We extracted the total yearly number of these tests: hemograms, activated partial thromboplastin time (APTT), prothrombin time (PT), international normalized ratio (INR), fibrinogen, endogenous and exogenous factors, anti-FXa activity (unspecified on type of heparin used), von Willebrand Factor ristocetin cofactor activity (VWF:RCo), D-dimer, and anti-platelet factor 4-heparin antibodies (anti-PF4/H). We then calculated the total person-years using demographic assessments from the National Institute of Statistics and Economic Studies.

Crude rates of test use per 100,000 habitants per year were calculated for each year. First, to have a starting point and to be as free as possible from bias due to potential variations of these tests prior to COVID-19, we used the nonparametric Mann–Kendall pattern test to assess whether or not the time series data had a statistically significant trend between 2013 and 2019. Then, to evaluate the impact of COVID-19 emergence on selected tests, we performed descriptive statistics between the number of tests performed between 2019 and 2020 and between 2020 and 2021. Statistical analysis was performed using RStudio (version 4.1.1).
Between 2013 and 2021, a total of 810,421,768 tests were collected for 600,602,171 patients. During the pre-COVID-19 era between 2013 and 2019, we noted a gradual increase per year in the number of hemograms (+15%, p < 0.01), PT (+3%), fibrinogen (+9%, p < 0.01), D-dimer (+247%, p < 0.01), VWF:RCo (+64%, p < 0.01), FVIII (+48%, p < 0.01), FIX (+53%, p < 0.05), FXI (+53%, p < 0.05), and exogenous coagulation factors assays ordered per 10,000 habitants (respectively FII +279%, p < 0.01; FV +358%, p < 0.01; FVII +452%, p < 0.01 and FX +442%, p < 0.01), whereas the number of anti-Xa activity (p > 0.05), PF4/H antibodies (p > 0.05), and FXII (p > 0.05) ordered per 10,000 habitants remained stable (Fig. 1). In contrast, we observed a gradual decrease of INR (−42%, p < 0.01), APTT (−3%, p < 0.05) ordered per 100,000 habitants.

During the first two waves of COVID-19 in France in 2020, the number of test reimbursements sharply decreased compared with 2019, particularly for INR, APTT, PT, and fibrinogen. In a meta-analysis, Uaprasert et al.19 observed that the incidence of HIT in COVID-19 patients was comparable to those without COVID-19. Since mass vaccination campaigns started in December 2020, several thrombotic events following COVID-19 vaccination were reported, as well as cases of vaccine-induced thrombotic thrombocytopenia (VITT).18,21

D-dimer testing has to be interpreted along with a whole clinical assessment. As critically discussed by Akima et al.,18 D-dimer testing has to be interpreted along with a whole clinical assessment.

During the first two waves of COVID-19 in France in 2020, the number of test reimbursements sharply decreased compared with 2019, particularly for INR, APTT, PT, and fibrinogen. This can be explained by the lower activity related to the first lockdown of the COVID-19 pandemic, with a significant decrease in global surgical activity and related preoperative hemostasis tests in 2020 and the reorganization of non-ICU wards.16 Nonetheless, the most striking decrease remains that of INR, which reflects that a significant number of patients were unable to monitor their INR in medical laboratories.

As critically discussed by Akima et al.,18 D-dimer testing has to be interpreted along with a whole clinical assessment. As critically discussed by Akima et al.,18 D-dimer testing has to be interpreted along with a whole clinical assessment.

To conclude, the COVID-19 pandemic had a very important effect on hemostasis test trends, with a decrease in the majority of assays due to lockdowns and health care system reorganization but a strong increase in D-dimer assays due to COVID-19-associated coagulopathy, in association with hemograms and anti-PF4/H likely due to VITT suspicion and disinformation in 2021.

Author Contributions
N.K.B. and N.G. designed the project. N.K.B., R.C., and N.G. performed the analysis and analyzed the data. N.K.B., N.G., and A.P. wrote the paper. N.G. and D.M.S. supervised the work and reviewed the paper. All other authors reviewed the paper.
