Successful removal of a fractured pancreatic stent using a novel thin-tapered drill dilator

Introduction
Endoscopic pancreatic stenting is performed to prevent main pancreatic duct obstruction and relieve painful symptoms of chronic pancreatitis. In some cases, it is quite challenging to remove pancreatic stents using devices such as forceps, balloons, and snares. We herein report a case in which a fractured pancreatic stent was successfully retrieved using a novel thin-tapered drill dilator after failed removal using various other devices.

A 51-year-old man with chronic pancreatitis was admitted for exchange of an obstructed 10F pancreatic stent. We were unable to negotiate a guidewire through or beside the stent. We used a snare to remove the stent; however, the stent did not move and eventually fractured. The fractured pancreatic stent could not be removed using forceps, a Soehendra stent retriever or a 3-mm-wide thin-tipped balloon catheter. The stent was completely obstructed, and we were unable to pass the guidewire over it. Therefore, we inserted a novel tapered drill dilator inside the stent and twisted the dilator. The stent clung to the dilator and was successfully retrieved with no adverse events. Finally, we inserted a new pancreatic stent.

Conclusion
The technique described here using this thin-tapered drill dilator might be a useful option for removing a pancreatic stent.

Soehendra stent retriever (Cook Medical Inc., Bloomington, Indiana, United States), or a 3-mm-wide thin-tipped balloon catheter (REN Biliary Balloon Dilation Catheter; Kaneka Corporation, Osaka, Japan) [4]. The stent was completely obstructed, and we were unable to pass the guidewire over it. Therefore, we inserted a novel tapered drill dilator (Tornus ES; Asahi Intecc, Aichi, Japan) into the stent and twisted the dilator. The stent clung to the dilator and was successfully retrieved using a novel thin-tapered drill dilator after failed attempts at removal using various other devices.

cessfully retrieved with no adverse events (▶Fig.2, ▶Video 1). Finally, we inserted a new pancreatic stent. This novel drill dilator was developed to facilitate endoscopic ultrasound-guided interventions (▶Fig.3) [5]. Because the device does not require strong pressing, excessive pressure against target organs can be avoided. In the present case, we completed the procedure without damaging the pancreas or inducing upstream migration of the pancreatic stent toward the main pancreatic duct. Furthermore, the dilator is thin-tapered and easy to insert. The technique described here using this thin-tapered drill dilator might be a useful option for removing a pancreatic stent.
