Supported Peptide for Asymmetric $\alpha$-Oxyamination of Aldehydes

**Significance:** A polystyrene-poly(ethylene glycol) resin supported peptide catalyst bearing terminal five-residue Pro-D-Pro-Aib-Trp-Trp combined with polyethylene was prepared. The polymeric peptide was successfully applied to the asymmetric $\alpha$-oxyamination of aldehydes with TEMPO in the presence of a catalytic amount of FeCl$_2$ and NaNO$_2$ to give the corresponding products under aqueous aerobic conditions with up to 87% yield and 93% ee (5 examples).

**Comment:** The Kudo group has previously reported asymmetric hydrogenation (K. Akagawa et al. *Tetrahedron: Asymmetry* 2009, 20, 461; K. Akagawa et al. *Org. Lett.* 2008, 10, 2035) and asymmetric Friedel–Crafts alkylation (K. Akagawa et al. *Tetrahedron Lett.* 2009, 50, 5602) in aqueous media with this catalyst. The polyethylene moiety between the tryptophan and the resin support not only provides a hydrophobic environment, but also effects the stereoselectivity of the reaction.
