Retention of endoscopic capsule in an umbilical hernia

Capsule endoscopy is a common method for the investigation of obscure gastrointestinal bleeding. Despite the reduced risk of complications, capsule retention is the most frequent complication, occurring in 1%–3% of cases [1].

A 64-year-old woman, obese and hypertensive, with indeterminate colitis in remission for several years, presented to the emergency department with hematochezia. She reported a history of recent surgery to varicose veins of the lower limbs and post-operative treatment with diclofenac. On physical examination, she appeared pale; the rest of the examination was unremarkable except for a reducible incoercible umbilical hernia. Analytically, the patient presented hemoglobin of 5.6 g/dL (12–16 g/dL).

Upper endoscopy and colonoscopy showed no lesions, and the patient was admitted for investigation. The computed tomography (CT) enteroclysis was normal except for an umbilical hernia with a bowel loop within, without signs of strangulation (Fig. 1).

Capsule endoscopy (PillCam SB 2; Given Imaging, Yoqneam, Israel) was then performed; it showed no changes in the mucosa up to the jejunum, where after 1 hour and 20 minutes the capsule remained stagnant until the end of the battery’s life (Fig. 2).

The patient remained asymptomatic. A small-bowel radiograph with water-soluble contrast showed the capsule retained in relation to an umbilical hernia (white arrow) (Fig. 3).
in the umbilical hernia and ruled out ste-nosis or signs of small-bowel obstruction (Fig. 3).
After 16 days of capsule retention, a her-

nioplasty was performed and the capsule was spontaneously expelled afterwards.
Retention of an endoscopic capsule is a rare complication. There are a few case re-
ports of capsule retention in different types of digestive diverticulum [2–4] but, to the best of our knowledge, this is the first case of capsule retention in an umbilical hernia. Current recommendations do not consider these entities as contra-
indications for capsule endoscopy [5], but the gastroenterologist should keep in mind the potentially increased risk of capsule retention.
