Abstract
Plant species have long been used as principal ingredients in traditional medicine. Different surveys showed that ethnomedicinal plant species used by the inhabitants of Jordan for the treatment of cancer are inadequately screened for their therapeutic/chemopreventive potential and phytochemical findings. In this mini review, traditional herbal medicines pursued indigenously with their methods of preparation and active constituents are listed. Studies of random screening for selective cytotoxicity and antiproliferative activity of local spices, domesticated greens, or wild plants are briefly discussed. Recommended future directives for the design and conduct of comprehensive trials are pointed out to validate the usefulness of these active plants or bioactive phytoconstituents either alone or in combination with existing therapies or complementing pharmacologies.

Introduction
The Hashemite Kingdom of Jordan’s habitat is unique in that the intersection of dense forest, arid desert, and tropical geography endows the country with a rich variety of plants and microorganisms that can be studied efficiently in a relatively small land area (Fig. 1) [1]. More than 2500 wild plant species from 700 genera exist; of these, there are approximately 100 endemic species, 250 rare species, and 125 very rare species [1–3]. In the Mediterranean basin, there seems to be a wealth of ethnobotanical studies providing a new and key tool for a quest after invaluable phytopharmaceuticals or the development of functional foods or nutraceuticals [4–12]. Traditional medicine practices are part of the Jordanian culture. Despite modern medicine accessibility, herbal medicine has often maintained popularity [13]. The percentage of reliability on herbal medicine varies from rural and desert areas to urban ones [14–16]. Crucially, the folk phytotherapy is “aging” or “vanishing” in the sense that knowledge of medicinal plants persists mainly in elderly rural people with little schooling [17]. In the last decades negative human impacts also affected the ecosystem, adding more plants to the list of endangered species, thus calling on the urgent need for community-based programs promoting their national conservation and sustainability [18].

In a survey carried out with the herbalists in Jordan, none of the interviewed herbalists mentioned any plants for the treatment of cancer [15]. On the other hand, literature surveys based on the published studies indicated that in Jordan and in the neighboring countries, 27 plant species are considered as traditional remedies for the treatment of the different types of cancers [14, 19–23]. This article summarizes information on different aspects of chemopreventive-therapeutic plants as well as randomly screened plants for the antiproliferative activity to stimulate interest in these herbs which are of importance in Jordan and other countries of the semi-arid tropics.

Results and Discussion
Cancer is a leading cause of death worldwide. More than 70% of all cancer deaths occurred in low- and middle-income countries. Deaths from cancer worldwide are projected to continue rising, with an estimated 12 million deaths in 2030 [24]. Running second after heart diseases, cancer is a major cause of morbidity among the Jordanian population, with an estimated incidence rate of...
5000 new cases per year. Male to female ratio for cancer cases in Jordan is 0.97:1. The overall median age of cancer diagnosis in Jordan is 56 years (males: 60 years; females: 52 years). 43.15% of all newly registered cases occurred in the age of 60 years and above, and 11.6% occurred below the age of 30 years [25].

As recently updated by the Jordan National Cancer Registry (JNCR) statistics, the most commonly diagnosed cancers in a descending order in 2008 would be breast (18.8%), colon (7.7%), lung (7.7%), bladder (4.3%), and non-Hodgkin's lymphoma (4.8%) [25,26].

The evidence-based practices of consuming plants and plant derived products in the treatment of cancer with the orthodox therapy were first reported by Afifi et al. [13]. In cooperation with the King Hussein Cancer Centre (KHCC), the researchers interviewed a total of 1138 randomly selected cancer outpatients, predominantly Jordanians. Among interviewees, the total number of complementary and alternative medicine (CAM) users was 404 (35.5%). All CAM users were either on chemotherapy or radiotherapy and preferred to use the crude extract in the form of infusions (n = 296, 73.3%) [13]. Crude extracts were prepared from coarsely powdered plant mixtures and none of the individual plants could be identified by the researchers. Therefore emphasis is given in the present review to the plants with claimed anticancer activities in the ethnopharmacological studies and to the findings of the random screening of the plant species from the local flora for their antiproliferative activities. Table 1 lists the ethnopharmacologically promoted plants with the method of preparation; parts used and reported phytochemical constituents. Clearly, in half of them, experimental studies to prove their cytotoxicity properties, however unique, are negligible. The majority of the plants (78%), nevertheless, were tested for other pharmacological activities (Table 1).

In an attempt to screen the medicinal herbs from the Jordanian flora collected from each of the four biogeographic regions of Jordan, more than 120 ethanol, chloroform, and water extracts belonging to about 49 families representing 86 genera were evaluated for their antiproliferative activity. *Impatiens noli-me-tangere* and *Impatiens parviflora* displayed remarkable antiproliferative activity on *MCF-7* cell lines and were pursued [40–44]. Alkaloids of the colchicinoid structural class are well known from this genus, particularly from *I. noli-me-tangere*, *I. parviflora*, and *I. walleriana* [41]. Martini et al. [42] evaluated extracts of ethnomedicinal plants from Jordan for their antiproliferative and cytotoxic activities against a panel of human tumor cell lines. Many of these agents target multiple signal transduction pathways; mod-

ulating cancer aneuploidy, tubulin binding, topo-isomerasers, and gene specific and aspecific targets, which vary widely depending on cancer origin \([12,50,51]\). The introduction of synthetic analogues of natural compounds may be a solution for potency and bioavailability limitations \([52]\). Some natural compounds have exhibited synergism with established chemopreventive agents or with other natural compounds \([53]\). Since drug associated toxicity remains a significant barrier for currently available chemotherapeutic and chemopreventive drugs, using natural compounds (with better safety profiles) as adjuvant therapy with current chemotherapeutic agents may help to mitigate drug associated toxicities \([54]\). The key challenge to researchers is how to best use this information for effective cancer prevention in populations with different cancer risks.

In conclusion, these studies, uniquely indicating the potential use of medicinal plants as antineoplastic agents, are among the very few that explored Jordanian flora from extreme environments such as the desert and near the Dead Sea (400 m below sea level) for pharmaceutical leads. Comprehensive research aiming at fully exploiting any of the promising species from the Jordanian flora, either alone or in combination with existing therapies, might lead to the discovery of new avenues for medicinal plants/natural compounds in reducing the public health impact of major cancers. Elucidation of molecular targets and mechanisms also constitutes another prerequisite.
