Diabetes mellitus (DM), the world’s most common metabolic disorder, results from a defect in insulin secretion, insulin action, or both [1]. It is projected that the global prevalence of diabetes is escalating. At least 250 million individuals worldwide suffer from diabetes, and this number will double by 2030. Increases in complications will undoubtedly follow increasing pervasiveness of diabetes [2].

The regional prevalence of diabetes in MENA (Middle Eastern and North Africa) countries is 7.7% [3]. Standing at 10.1%, Jordan has the ninth highest incidence of diabetes. Several national surveys indicated that the prevalence of type 2 diabetes and impaired fasting glycemia is in an unprecedented increase with an epidemiological transition in Jordan [4–6]. More than 80% of diabetes deaths occur in low- and middle-income countries. Endocrine, nutritional, and metabolic diseases represent 7.9% of deaths in Jordan [7–8]. Located in the Middle East, Jordan covers 92,300 km² with high geographical and ecological diversity. Its varied topography and climate result in the junction of four biogeographical regions Fig. 1S, and these crossroads engender the country with substantial biodiversity that is at large understudied or, even worse, left unexplored [9].

In Jordan, where traditional medicine plays a partial role in imparting the primary health care, vegetables, culinary herbs, and medicinal plants are among the main choices in the management of diabetes [13, 14]. However, it is officially neither integrated in the health care system nor recognized in national policies of the country. The objective of this mini review is to underline the ethnopharmacological practices related to 30 selected ethnobotanicals with claimed antidiabetic properties in light of their comprehensive scientific evaluation.

Abstract

Diabetes mellitus is the most common metabolic disorder affecting millions worldwide. It is recognized as a global major health problem. As alternatives to the available orthodox medicines, plants are considered a potential source for the treatment of diabetes within traditional ethnomedicine practices. In theJordanian traditional medicine a significant selection of ethnobotanicals is promoted for their antidiabetic activity. Literature surveys demonstrate the benefit of several ethnobotanicals as antidiabetic agents evaluated in in vitro and in vivo systems in the form of their crude extracts and/or isolated pure compounds with varying degrees of hypoglycemic or antihyperglycemic bioactivities. This mini review discusses the preparatory forms in which these plants are consumed, their reported phytoconstituents, and the results of their reported antidiabetic bioactivity.

Introduction

Diabetes mellitus (DM), the world’s most common metabolic disorder, results from a defect in insulin secretion, insulin action, or both [1]. It is projected that the global prevalence of diabetes is escalating. At least 250 million individuals worldwide suffer from diabetes, and this number will double by 2030. Increases in complications will undoubtedly follow increasing pervasiveness of diabetes [2].

The regional prevalence of diabetes in MENA (Middle Eastern and North Africa) countries is 7.7% [3]. Standing at 10.1%, Jordan has the ninth highest incidence of diabetes. Several national surveys indicated that the prevalence of type 2 diabetes and impaired fasting glycemia is in an unprecedented increase with an epidemiological transition in Jordan [4–6]. More than 80% of diabetes deaths occur in low- and middle-income countries. Endocrine, nutritional, and metabolic diseases represent 7.9% of deaths in Jordan [7–8]. Located in the Middle East, Jordan covers 92,300 km² with high geographical and ecological diversity. Its varied topography and climate result in the junction of four biogeographical regions Fig. 1S, and these crossroads engender the country with substantial biodiversity that is at large understudied or, even worse, left unexplored [9].

In Jordan, where traditional medicine plays a partial role in imparting the primary health care, vegetables, culinary herbs, and medicinal plants are among the main choices in the management of diabetes [13, 14]. However, it is officially neither integrated in the health care system nor recognized in national policies of the country. The objective of this mini review is to underline the ethnopharmacological practices related to 30 selected ethnobotanicals with claimed antidiabetic properties in light of their comprehensive scientific evaluation.
Discussion

Surveys based on interviews with herbalists and search engines indicated that in the Jordanian traditional medicine almost 70 plant species belonging to 38 families were consumed by diabetic patients. The majority of the used plants are native to Jordan while others like Zingiber officinalis, Terminalia chebula, or Emblica officinalis are recognized as plants of nonindigenous origin [13, 15–17]. Reports on the concomitant use of plants accompanying the orthodox therapy are limited. Primarily, interviews with diabetes patients in specialized health centers of Jordan further signified a more diversified list of selected plants [14, 18]. The reported plants were: Camellia sinensis, Pimpinella anisum, Zingiber officinale, Matricaria chamomilla, Salvia triloba, Trigonella foenum-graecum, Nigella sativa, Lupinus albus, Teucrium polium, Allium sativum, Cinnamomum zeylanicum, and Olea europea. Locally, a preliminary screening of the critical pharmacological appraisal of the traditionally utilized botanicals was performed. It demonstrated that reports on diabetes interventional phytotherapies are scarce. Gharabeh et al. [19] investigated the hypoglycemic effects of Teucrium polium in normal and STZ-diabetic rats. Hamdan and Afifi [20], Afifi et al. [21], and Kasabri et al. [22, 23] undertook a comprehensive and complementary in vitro and in vivo testing for a vast array of indigenously recruited herbs, partially consumed as integral to the diet of the traditional communities; Achillea santolina, Eryngium creticum, Geranium graveolens, Paronychia argentea, Pistacia atlantica, Rheum ribes, Sarcopoterium spinosum, T. polium, and Veratrum album have been identified as antidiabetic phytomedicines. This line of research findings could link and rationalize the ethnopharmacological use with new approaches in the prevention/modulation of postprandial hyperglycemia emerging from the therapeutic use of α-amylase and α-glucosidase inhibitors. Also, Al-Mustafa and Al-Thunibat [24] investigated the antioxidantative potentialities of an extensive list of Jordanian antidiabetic phytomedicines. Moreover, pancreatic mechanistic studies were reported for the hypoglycemic bioactivities of cinchonain Ib from Eriobotrya japonica [25] and Ferula asafoetida [26]. Additionally, the hypoglycemic effects of Ballota nigra [27] and Artemisia sieberi [28] were evidenced in alloxaan-diabetic rats. Comparable to conventional diabetes pharmacotherapeutics, the significant efficacy of hypoglycemic herbs is achieved by increasing insulin secretion, enhancing glucose uptake by adipose and muscle tissues, inhibiting glucose absorption from intestine and inhibiting glucose production from hepatocytes [29–31]. Certain herbs may ameliorate overt hyperglycemia substantially in clinical trials with well characterized action mechanisms [32, 33]; their test results, however, are subject to several factors. Firstly, each herb contains multiple compounds, only a few of which may be therapeutically effective either alone or synergistically [34]. Secondly, different parts of an herb have different ingredient profiles. Thirdly, different extraction methods may yield different active ingredients [35]. Most recently, the antidiabetic activity of several flavonoids, polyphenols, terpenoids, coumarins and some alkaloids have been reviewed [36–39]. The reported secondary metabolites of the selected 30 plants are listed in Table 1. Especially important in the present review, flavonoids are the major class of secondary metabolites detected in most of the plants. Moreover, terpenoids have been reported in the discussed plant species with hypoglycemic activities [29, 30]. Locally, one of the common practices is to assign certain species of a given genus a single common Arabic name with the expectation that all of them will perform ethnopharmacologically equally. This unjustifiable practice is based on species availability. In application, and despite scientific invalidity, the three Artemisia, both Cichorium spp., and the two Crataegus species have been the subject of such inappropriate convenience of designation. Plants compiled in Table 1, demonstrating antidiabetic pharmacological activities, can be subgrouped as follows:

1. Spices: (M. spicata, O. syriacum, L. nobilis, C. sativum, C. cymum, C. spinosa). Spices do not only improve the taste of the foods but do also contribute to the well-being of humans. Influence of the spices on the body metabolism and on the endocrine system has gained importance in the recent years. Numerous spices have been evaluated in animal experiments as well as clinical studies, and evidence has been obtained for their antidiabetic potential [40–43].

2. Vegetables and fruits: (Cichorium intybus, C. pumilum, Opuntia ficus indica, Allium cepa Portulaca oleracea, Crataegus aronia, C. azarolus, Citrus limon, C. paradisi). Since appropriate diet, exercise, and weight reduction are essential in controlling the blood sugar, antidiabetic activities of many edible fruits and vegetables – in the form of aqueous and alcohol extracts – have been tested in diabetes animal models. Furthermore, clinical evidence for the antidiabetic activity is reported for two vegetables, namely for C. intybus and A. cepa. A. cepa exhibited hypoglycemic effects in type 1 and type 2 diabetic patients (Table 1). Exceptionally, C. intybus, possessing multiple action mechanisms in controlling the blood glucose level such as alpha amylose inhibitory activity, appetite regulation, and increasing insulin secretion (Table 1), has hypoglycemic activity in different animal models and clinically evidenced benefits in the reduction of diabetes risk (Table 1).

3. Medicinal herbs and nonedible parts of fruits: (Artemisia herba-alba, A. judaica, A. vulgaris, Citrullus colocynthis, Aloe vera, Eucalyptus globules, Plantago major, P. ovata, Ruta chalepensis, Eryngium creticum and C. sinensis, Ceratonia siliqua, Juglans regia, M. nigra). For A. herba-alba, hypoglycemic, antihyperglycemic, and preventive effects have been illustrated in various animal models of diabetes. Nevertheless, A. judaica exhibited antidiabetic effects in STZ-diabetic rats, but A. vulgaris used locally for its antidiabetic activity has not been appraised pharmacologically. The remaining medicinal herbs, with the exception of R. chalepensis, have established antidiabetic activities. Richness in flavonoids, such as rutin, may raise plausible anticipation for R. chalepensis antidiabetic potentiality (Table 1). Several studies indicated the hypoglycemic benefits of flavonoids such as hesperidin, quercetin, luteolin, naringenin, and rutin in STZ-diabetic rats [44–48]. Leaf decoctions of common fruit trees – C. siliqua, J. regia, and M. nigra – and the peels of C. sinensis are praised throughout the country for their antidiabetic activities. These substantial efficacies have been clearly verified. Moreover, the antidiabetic efficiency of C. siliqua leaf extracts has been confirmed in type 2 diabetic patients (Table 1).

Conclusion

Based on hundreds of years of belief and observation, a marked number of plant species are used by the inhabitants of Jordan for the treatment of diabetes. The traditional knowledge of plants

shown in relation to their medicinal use reflects a striking diversity of species and uses, as well as their importance in popular plant therapy. Pharmacologic and therapeutic evaluation of the selected plants in this review explicitly substantiates the ethnopharmacological practices in Jordan. These traditions could pave the way for future phytochemical and pharmacological studies, thereby contributing to alternative therapeutic strategies to available drugs with undesirable adverse effects or those lacking in satisfactory efficacy or safety.

Supporting information
In Table 15 of the Supporting information, the up-to-date reported pharmacological activities of the selected medicinal plants with claimed antidiabetic propensities are discussed. On the other hand, Table 1 includes the reported antidiabetic efficacy and/or action mechanism of the same selection of medicinal plants.

Conflict of Interest
The authors declare none.
