Closure of a persistent esophagopleural fistula assisted by a novel endoscopic suturing system

Gastrointestinal fistulas may be successfully managed endoscopically [1]. Novel endoscopic techniques for full thickness tissue approximation may serve as adjuvants for assisting fistula closure [2, 3]; an example is a flexible endoscopic suturing system [4]. We describe a case of a chronic esophageal fistula, treated previously with endoscopic clipping and esophageal stenting, which was successfully managed using a novel endoscopic suturing system [5].

A 66-year-old woman presented with a 3-month history of a chronic esophagopleural fistula secondary to Boerhaave syndrome. The fistula was initially drained by thoracostomy and subsequently treated with endoscopic clipping and esophageal stenting, which was successfully managed using a novel endoscopic suturing system [5].

previously. There was no contrast extravasation post suturing, and it was elected not to place a stent. The total procedure time was 90 minutes (20 minutes for the actual suturing procedure).

Follow-up endoscopy and contrast examination of the esophagus after the second suturing procedure showed complete fistula closure (Fig. 4).
