Amyloidosis is characterized by the extracellular accumulation of fibrillar proteins, which commonly shows systemic involvement. Localized amyloidosis is rare, especially regarding the stomach. The lesion may cause paresis, constipation, and bleeding [1–3]. We saw a case of gastric localized amyloidosis with bleeding, in which endoscopic resection was successfully done as a treatment for anemia.

A 77-year-old woman with chronic liver disease was referred to our hospital with anemia. Esophagogastroduodenoscopy revealed a flat, depressive lesion at the greater curvature of the lower gastric body (Fig. 1). The lesion bled easily after air inflation (Fig. 2).

Because the anemia could not be improved with conservative treatment, the lesion was removed by endoscopic submucosal dissection (Fig. 3). The lesion was 46 × 28 mm, and pathological examination showed amyloid deposits in the mucosal and submucosal layer (Fig. 4). The material stained positive with direct fast scarlet (DFS). The positivity with DFS staining was not affected by pretreatment with potassium permanganate, suggesting the possibility of amyloid light-chain (AL) type amyloid protein. Serum amyloid A was normal (5.5 μg/mL; normal range 0–8.0 μg/mL).

After treatment, the ulcer had formed a scar, and the patient’s anemia improved (Fig. 5).
