Total Synthesis of Neurymenolide A

Significance: Neurymenolide A is an unusual α-pyrene macrolide that was isolated in 2009 from the Fijian red alga Neurymenia fraxinifolia, exhibiting a broad scope of biological activity. This work represents the first total synthesis of the natural product and features a series of remarkably selective transition metal-catalyzed transformations to build up the highly sensitive cyclophane scaffold.

Comment: The route is based on a novel gold-catalyzed pyrone synthesis that allowed for selective alkyne activation within intermediate F. α-Pyrene H was subjected to efficient alkyne metathesis to construct macrocycle J. Neurymenolide A acetate (K) exists as a mixture of interchanging atropisomers and the synthetic material obtained was identical to a sample derived from natural sources. Deprotection of K led to rapid degradation.
