trans-Selective Hydroboration of Internal Alkynes Catalyzed by Ruthenium

**Comment:** Both control and deuterium-labelling experiments provide support for a true trans-selective hydroboration, rather than an isomerization process. The proposed mechanism involves an inner-sphere hydride delivery to furnish metallocyclopropene *C*, which can relieve steric congestion about the Cp* ring via isomerization to metallocyclopropene *E*. The reductive elimination places the boron atom anti to the hydrogen atom, providing access to the E-configured olefin. While the method is highly functional-group-tolerant, modest regioselectivity is observed with unsymmetrical alkynes.
