Modified single-balloon endoscopy for ERCP in a patient with Billroth II gastrectomy

An 84-year-old man with a history of hepatocellular carcinoma treated by transcatheter arterial chemoembolization and percutaneous ethanol injection therapy 2 years previously was admitted with jaundice. Magnetic resonance cholangiopancreatography (MRCP) showed a tumor invading the bifurcation of the common bile duct with bilateral intrahepatic duct dilatation (Fig. 1). Endoscopic retrograde cholangiopancreatography (ERCP) was considered but as the patient had undergone a previous Billroth II gastrectomy and was concerned about possible complications, we held back from performing this procedure.

A modified single-balloon enteroscopy-assisted ERCP was planned instead, using a sliding tube with a balloon (XST-SB1; Olympus) and a balloon controller (XMAJ-1725; Olympus). The sliding tube has a working length of 132 cm, with outer and inner diameters of 13.2 mm and 11 mm respectively, and has a silicone balloon at its tip [1]. An adequate aperture was made in the overtube at a point 75 cm from its tip on the side opposite to the pressure line. A conventional forward-viewing upper gastrointestinal endoscope with this modified single balloon was used to perform ERCP by the standard single-balloon method (Fig. 2). The papilla was found via the afferent loop and a plastic stent was successfully placed with no complications (Fig. 3 and Fig. 4).

It is usually difficult to perform ERCP in postoperative patients because of their altered anatomy. Balloon-assisted enteroscopy, with either a double or single balloon, can be used for these patients [1,2]. Although single-balloon enteroscopy-assisted ERCP is an accepted method, some endoscopists believe that “short-type” double-balloon enteroscopy is more effective in such patients [3]. In one multicenter experience of overtube-assisted enteroscopic ERCP in patients with surgically altered pancreaticobiliary anatomy, the overall success rates were 60% and 63% in single-balloon and double-balloon procedures respectively. There was no significant difference between ERCPs performed by single-balloon or double-balloon enteroscopy [4].

There are many published case reports using double-balloon enteroscopy for ERCP in patients with altered anatomy, but reports of single-balloon enteroscopy-assisted ERCPs are rare [1,5,6]. One reason for this is that double-balloon enteroscopy was developed before single-balloon enteroscopy. The other reason is that “short” double-balloon enteroscopy is easy to use for ERCP in patients with altered anatomy. Single-balloon enteroscopy has a 200-cm working length and the accessories are very limited [7].

Itoi et al. developed one possible method for single-balloon enteroscopy-assisted ERCP [1]. They performed traditional single-balloon enteroscopy first; they then made an aperture in the overtube at a point 100 cm from its tip. A conventional forward-viewing upper gastrointestinal endoscope was then substituted for the...
enteroscope before the ERCP. Their overall success rate for therapeutic ERCP was 76.9%; however, this is a complicated method.

Here, we report an easier method that we have developed for ERCP in patients with altered anatomy. We make an aperture in the overtube at a point 75 cm from its tip, which enables us to complete the balloon-assisted ERCP with a conventional forward-viewing upper gastrointestinal endoscope—the enteroscopy is unnecessary in our method. The one limitation to our method is that it is not suitable for patients with a Roux-en-Y anastomosis because the loop from the anastomosis to the papilla is longer in this situation than after other types of surgery.
