An 87-year-old man with multiple medical co-morbidities was admitted for right upper quadrant pain and fever. Computed tomography showed a distended gallbladder with gallstones and pericholecystic fluid compatible with a diagnosis of acute cholecystitis. There was no gallbladder mass. Since the patient had sepsis and was unfit for surgery, endoscopic ultrasound (EUS) drainage of the gallbladder was performed with a lumen-apposing stent (10 × 15mm, AXIOS; Xlumena, Mountain View, California, USA) as an alternative to percutaneous cholecystostomy (Fig. 1a, b). The patient had an uneventful recovery.

Follow-up cholecystoscopy performed 3 months later showed clearance of all stones. However, a 2-cm polypoid lesion was noted at the fundus of the gallbladder. Magnifying narrow band imaging (NBI) showed enlarged and irregular mucosal glands with dilated and corkscrew-appearance microvasculature that was suspicious for malignancy (Fig. 2). Probe-based confocal laser endomicroscopy (CLE) (GastroFlex; Mauna Kea Technologies, France) showed darkened and irregular columnar cells with loss of villous architecture (Fig. 3a, b). Miniprobe EUS examination (UM-DP12 – 2SR; Olympus, Tokyo, Japan) showed suspicion of tumor involvement of the gallbladder muscularis propria (Fig. 4). Final histological findings confirmed the presence of a gallbladder adenocarcinoma (Fig. 5). The patient was then treated conservatively as he was too frail to undergo any major surgery.

To our knowledge, this is the first description of a gallbladder adenocarcinoma discovered endoscopically. This was made possible through the use of endosonographic drainage that allowed endoscopic assessment of the gallbladder [1, 2]. Magnifying NBI endoscopy has revolutionized the diagnosis of early gastrointestinal neoplasms and is pivotal to performance of endoscopic mucosal resection or submucosal dissection [3]. CLE allows in vivo assessment of cellular architecture and has been shown to be associated with high sensitivity and specificity for diagnosis of Barrett’s metaplasia and biliary malignancy [4]. EUS-guided gallbladder drainage in this patient opened the way for application of the above instruments in aiding diagnosis that was not suspected on CT.
