Introduction

Metal-free organocatalysis employing N-heterocyclic carbenes (NHCs) has attracted great interest because of its use in the construction of intricate molecular architectures from simple starting materials under mild reaction conditions. The catalytic pathway of NHCs mimics that of thiamine-dependent enzymatic processes and passes through discrete reactive species, such as acyl anions and enolate or homoenolate equivalents. This enables the selective generation of a set of versatile electrophilic (acyl azoliums) and nucleophilic (enolates, homoenolates) intermediates and makes NHCs efficient catalysts in such various reactions as acylation, cycloaddition, β-borylation, and elimination.

N-Mesityl substituted imidazolium (cat. A) and triazolium (cat. B and C) salts were introduced by Bode and co-workers as stable NHC precursors. The imidazolium derivative favors the homoenolate pathway, whereas the triazolium precursor promotes almost all NHC-catalyzed transformations, except for benzoin and Stetter reactions. Chiral pre-catalysts like C and its enantiomer are also commercially available. It should be noted that the N-substituent is of crucial importance; for example, an N-phenyl substituents might not provide any product, while the Bode (N-mesityl) or Rovis (N-pentafluorophenyl) catalysts are highly catalytically active.

Abstracts

(A) Bode catalysts were first found to be efficient for the esterification of aldehydes via the activated carboxylates generated from α,β-epoxyaldehydes, enals, and cyclopropanes. You et al. used a similar methodology for the ring expansion of formylcyclopropanes to afford 3,4-dihydro-α-pyrone s. Although in situ generated acyl azoliums did not react directly with amines, amidation was possible using a co-catalyst with additives such as imidazole, triazole, hydroxamic acid, HOBT, HOAt, or pentafluorophenol. This approach was successfully in the catalytic kinetic resolution of cyclic amines using the chiral hydroxamic acid 1 or 2 as co-catalyst. Recent development includes the use of a polymer-supported histidine-bound NHC precursor in which the histidine moiety acts as co-catalyst.
(B) Ester enolate equivalents generated from α-halo- and αβ-unsaturated aldehydes underwent enantioselective oxa- and aza-Diels–Alder reactions. Strikingly, bench-stable bisulfite adducts of α-halo aldehydes could be directly used for this transformation. Kobayashi et al. reported the synthesis of 1β-methylcarbapenem antibiotic intermediates using vinyllogous amides as dienes.

(C) Although imidazolium-derived catalysts are generally superior to triazolium precursors in γ-lactonization and γ-lactamization reactions, triazolium salts also efficiently promote the annulation of highly reactive electrophiles via the homoenoelate pathway. In 2013, Chi et al. developed a selective β-protonation of homoenoelate equivalents. This enabled the synthesis of previously inaccessible enolates by the reaction of enals with chalcones.

(D) In course of their work on kojic acids, Bode and co-workers discovered a new enantioselective azadiol-catalyzed annulation of ynals via a Coates–Claisen rearrangement. The reaction pathway was different from enolate, homoenoelates, and acyl anion activation. Further, the substrate scope of the reaction was extended to enals. Mechanistical insights into this transformation led to the NHC-catalyzed aza-Claisen rearrangement of enals with vinylogous amides.

(E) The NHC-promoted addition of enals to imine electrophiles represents a particular reactivity. Ketimines derived from saccharine (methylcarbapenem anti-биотic intermediates using vinylogous amides as dienes. The NHC-promoted addition of enals to imine electrophiles represents a particular reactivity. Ketimines derived from saccharine (methylcarbapenem anti-

(F) Recently, Alexakis and co-workers reported the stereoselective annihilation between α-cyano-1,4-diketones and ynals. Starting from achiral material and in the presence of achiral pre-catalyst B, this transformation furnished a functionalized bicyclic scaffold possessing three contiguous stereogenic centers with a good diastereoselectivity.
