Severe colitis related to granulomatosis with polyangiitis (Wegener’s granulomatosis)

A 58-year-old man presented with weakness, cough, weight loss, and intermittent painless rectal bleeding for 2 weeks. He was on no medication and gave no history of smoking or alcohol use. His family history was unremarkable. On examination, his abdomen was soft and diffusely tender. Thoracic computed tomography (CT) scan showed bilateral perihilar infiltration, and ground-glass opacities and areas of consolidation in the middle right and left lobe (Fig. 2).

Because of the high suspicion of ischemia on colonoscopy, angiography was performed. This showed incomplete stenosis in the proximal portion of the left internal iliac artery (Fig. 3).

The patient was diagnosed as having granulomatosis with polyangiitis (GPA). GPA, also known as Wegener’s granulomatosis, is an idiopathic ANCA-positive vasculitis involving vessels of small and medium size in many organs [1]. The respiratory tract, lungs, and kidneys are the organs most often affected; it very rarely involves organs of the gastrointestinal system. Gastrointestinal involvement has been described in 10%–24% of patients with GPA [2]. From the reports in the literature, cases respond well to intensive immunosuppressive treatment [3], but close follow-up is required to monitor for relapse and determine the involvement of other organs.
