A 58-year-old man presented with weakness, cough, weight loss, and intermittent painless rectal bleeding for 2 weeks. He was on no medication and gave no history of smoking or alcohol use. His family history was unremarkable. On examination, his abdomen was soft and diffusely tender. His respiratory tract, lungs, and kidneys are the organs most often affected; it very rarely involves organs of the gastrointestinal system. Gastrointestinal involvement has been described in 10%–24% of patients with GPA [2]. From the reports in the literature, cases respond well to intensive immunosuppressive treatment [3], but close follow-up is required to monitor for relapse and determine the involvement of other organs.
