Abstract Flash vacuum pyrolysis (FVP) at $500-600^{\circ} \mathrm{C}$ of 1 -substituted pyrazolylaminomethylene derivatives of Meldrum's acid provides 1-substituted pyrazolo[3,4-b]pyridin-4-ones in high yields. If the 1 -substituent is a tert-butyl group, FVP at $750-850^{\circ} \mathrm{C}$ causes elimination of 2-methyl-1-propene to give the parent pyrazolo[3,4-b]pyridin-4-one.

Key words gas-phase reactions, pericyclic reactions, heterocycles, Meldrum's acid, medicinal chemistry

There are very few references to 1 -unsubstituted pyra-zolo[3,4-b]pyridin-4-ones 1 in the literature ${ }^{2}$ and all known derivatives except the parent compound $\mathbf{1}\left(R=R^{\prime}=H\right)$ have a substituent in the 6-position. Potential functionalization of the 4 -position (e.g., via the triflate or the 4 -chloro compound) would provide 4 -substituted pyrazolo[3,4-b]pyridines 2 (Figure 1), which have shown diverse application in medicinal chemistry. ${ }^{3}$ On the other hand, substitution at the 1-position generally results in loss of biological activity due to the disruption of the hydrogen bonding regime. ${ }^{4}$

Figure 1 1-Unsubstituted pyrazolo[3,4-b]pyridin-4-ones 1 and 4-substituted pyrazolo[3,4-b]pyridines 2

In earlier work, we explored a potential route to $\mathbf{1}$ by flash vacuum pyrolysis (FVP) of Meldrum's acid derivatives [e.g., $3\left(\mathrm{R}^{1}=\mathrm{H}\right)$ ], but cyclization of the imidoylketene intermediate $4\left(\mathrm{R}^{1}=\mathrm{H}\right)$ occurred exclusively at the adjacent ni-
trogen atom to provide a useful route to the pyrazolo[1,5a]pyrimidine system 5 (Scheme 1). ${ }^{5}$ Clearly this route must be blocked to provide pyrazolo[3,4-b]pyridin-4-ones.

Scheme 1

The present work therefore had a range of objectives. First, 3 ( $\mathrm{R}^{1}=$ alkyl or aryl) were synthesized and pyrolyzed to ensure that, in the absence of the pyrazole NH, cyclization onto the adjacent carbon atom to give $\mathbf{1}(\mathrm{R}=1$-alkyl or 1 -aryl) would take place (Scheme 1 ), as observed in many related systems. ${ }^{6}$ Second, we explored the design of a thermal N -protecting group, which would remain at low furnace temperatures, but be selectively removed at higher furnace temperatures to provide N -unsubstituted pyrazolopyridinones $\mathbf{1}\left(\mathrm{R}^{1}=H\right)$. If the previous stages were successful, we aimed finally to functionalize the 4 -position of the pyrazolo[3,4-b]pyridin-4-ones to establish that the route has significant potential for the synthesis of pyrazolo[3,4b]pyridines 2.

The 1 -substituted and 1,3-disubstituted 3-aminopyrazoles 6a-f (Figure 2) were either commercially available or were synthesized by known methods. Compounds $\mathbf{6 c},{ }^{7} \mathbf{6 e},{ }^{8}$ and $6 \mathbf{f}^{9 a}$ are known only in patents or are formed in poor yield; ${ }^{9 b}$ their full characterization data are given here. Compound $\mathbf{6 c}$ was formed as a $5: 1$ mixture of $\mathbf{6 c}$ and its 1 -tert-butyl-3-amino isomer, which was taken on to the next stage without purification. Reaction of 6a-f with methoxymethylene Meldrum's acid in acetonitrile gave the aminomethylene derivatives 3a-f (Figure 2) in 89-99\% yield and (generally) high purity. Compound $3 \mathbf{c}$ was purified by recrystallization before pyrolysis.

FVP of $\mathbf{3 a}$ and $\mathbf{3 b}$ at $600^{\circ} \mathrm{C}$ ( 0.03 Torr) gave 1-methylpyr-azolo[3,4-b]pyridin-4-one (1aa) (92\%) and its 3-methyl-1phenyl analogue 1ba (95\%), respectively, as involatile solids that crystallized at the exit point of the furnace. It is clear, therefore, that blocking the 1-position of the pyrazole has the effect of diverting the cyclization to the adjacent carbon atom to provide the target pyrazolopyridinones.

In order to access the 1 -unsubstituted pyrazolo[3,4b]pyridines $1\left(\mathrm{R}^{1}=\mathrm{H}\right)$, a thermally removable N -protecting group was required. If a retro-ene reaction is possible, an N -tert-butyl group is ideal because the only co-product is 2 -methyl-1-propene. We have exploited this in the pyridazin3 -one series ${ }^{10}$ and it is also known that $N$-tert-butylpyrazole (7) loses 2-methyl-1-propene at high temperatures (Scheme 2). ${ }^{11} \mathrm{~A}$ temperature profile of this reaction (Figure 3) shows that, in our apparatus, at temperatures below $600^{\circ} \mathrm{C}$ the N -alkyl product 7 is formed exclusively whereas at temperatures above $850^{\circ} \mathrm{C}$, only the deprotected product $\mathbf{8}$ was formed. It was therefore anticipated that FVP of 3c-f in the range $500-600^{\circ} \mathrm{C}$ should provide the $N$-tert-butyl products $1\left(\mathrm{R}^{1}=t\right.$-Bu) whereas FVP in the range $750-850{ }^{\circ} \mathrm{C}$ should provide the deprotected products $1\left(\mathrm{R}^{1}=H\right)$.

These predictions were borne out in practice. FVP of $\mathbf{3 c}$ f at $500^{\circ} \mathrm{C}$ gave the pyrazolopyridinones 1ca, 1da, 1ea, and 1fa (Figure 4) in $83-97 \%$ yields and at $750-850^{\circ} \mathrm{C}$ gave the deprotected products $\mathbf{1 c b}$ and $\mathbf{1 d b}$ in $67-82 \%$ yields whilst the more highly substituted derivatives $\mathbf{1 e b}$ and $\mathbf{1 f b}$ were

obtained as more complex mixtures. ${ }^{12}$ N-Unsubstituted pyrazolopyridinones show exceptionally broad peaks in their NMR spectra due to tautomerization, but the two NH resonances at ca. $\delta_{H}=12.8-13.8$ and 11.5-11.8 are characteristic, as previously reported. ${ }^{2 a}$

As an alternative to the one-pass cyclization-deprotection described above, the protecting group can be retained prior to functionalization of the 4 -oxo substituent. This strategy is illustrated for the 3-phenyl series $\mathbf{1 e}$, which was chosen as it might prove unreactive owing to peri interactions with the 3 -substituent.

Thus, treatment of 1ea with phosphoryl chloride gave the 4 -chloro compound $\mathbf{9}$ (99\%), which could either be thermally deprotected to $\mathbf{1 0}$ (87\%), or reacted further. For example, reaction of $\mathbf{9}$ with pyrrolidine in the absence of a catalyst provided a low yield of the pyrrolidino compound $\mathbf{1 1}$ (37\%); alternatively, reaction with aniline under Buchwald-

Hartwig conditions gave the anilino compound 12 (87\%), which could be thermally deprotected to 13 (72\%) (Scheme $3)$.

Scheme 3

In conclusion, the work described here has provided a flexible gas-phase route to pyrazolo[3,4-b]pyridin-4-ones and pyrazolo[3,4-b]pyridines. An important feature of the strategy is the use of an $N$-tert-butyl group, which may be retained at low furnace temperatures (allowing functionalization of the 4-oxo group) or removed at high furnace temperatures to provide a one-pass route to N -unsubstituted analogues.

## 5-Amino-1-tert-butyl-1H-pyrazole (6c) ${ }^{7}$

tert-Butylhydrazine hydrochloride ( $5.99 \mathrm{~g}, 48.1 \mathrm{mmol}$ ) was added to $\mathrm{EtOH}(60 \mathrm{~mL})$ to form a slurry. To this was added $\mathrm{NaOAc}(7.93 \mathrm{~g}, 96.7$ mmol ) and 2-chloroacrylonitrile ( $5 \mathrm{~mL}, 62.6 \mathrm{mmol}$ ). The solution was heated to $80^{\circ} \mathrm{C}$ for 18 h , cooled, and the solvent removed in vacuo. The residue was slowly diluted with distilled $\mathrm{H}_{2} \mathrm{O}(35 \mathrm{~mL})$ and partitioned between sat. aq $\mathrm{NaHCO}_{3}(40 \mathrm{~mL})$ and $\mathrm{EtOAc}(40 \mathrm{~mL})$. The organic layer was separated and the aqueous layer was extracted with EtOAc ( $2 \times 20 \mathrm{~mL}$ ). The organic layers were combined, washed with brine ( 20 mL ), dried $\left(\mathrm{MgSO}_{4}\right)$, and the solvent removed in vacuo to afford a red oil; yield: $7.95 \mathrm{~g}(91 \%)$; bp $93-94^{\circ} \mathrm{C} / 0.9$ Torr (yellow liquid). The product was a $5: 1$ mixture of the title compound $\mathbf{6 c}$ and its 1-tert-butyl-3-amino isomer. The crude product was used to prepare the Meldrum's acid derivative $\mathbf{3 c}$, which was purified by recrystallization (see below).

## FVP Reactions

Flash vacuum pyrolysis reactions were carried out by distillation of the substrate in vacuo through an electrically heated silica furnace tube ( $35 \times 2.5 \mathrm{~cm}$ ). Products were trapped in a U-tube situated at the exit point of the furnace and cooled with liquid $\mathrm{N}_{2}$. Conditions were first established on a small scale ( 20 mg ) where the product(s) were dissolved in a deuterated solvent and analyzed directly by ${ }^{1} \mathrm{H}$ NMR spectroscopy. Larger-scale pyrolyses, involving 0.1 g or more of substrate, were usually removed from the trap by solution in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ (30 mL ). The precursors and pyrolysis conditions [quantity of precursor, inlet temperature $\left(T_{\mathrm{i}}\right)$, furnace temperature $\left(T_{\mathrm{f}}\right)$, pressure range $(P)$, and pyrolysis time $(t)]$ and yields are stated.

## 1-tert-Butyl-3-phenyl-4-(pyrrolidin-1-yl)-1H-pyrazolo[3,4-b]pyridine (11)

Pyrrolidine ( $1.0 \mathrm{~mL}, 11 \mathrm{mmol}$ ) was added to a solution of 9 ( 250 mg , 0.877 mmol ) in 1,2-dimethoxyethane ( 15 mL ) and the mixture was heated at reflux with stirring for 18 h . The solvent was removed and the residue was partitioned between sat. aq $\mathrm{NaHCO}_{3}(25 \mathrm{~mL})$ and EtOAc ( 25 mL ). The organic layer was separated and the solvent removed in vacuo to yield an orange residue, which was purified by dry flash chromatography eluting with hexane-EtOAc (20:1).
