Abstract A low-cost and high-yielding synthetic route towards methyl 4-pentafluorosulfanylphenyl sulfoximines from the corresponding sulfide has been developed. The intermediate N-cyano sulfoximine was converted into the corresponding NH-tetrazole, and the NH-sulfoximine was modified by N-arylation and N-alkylation reactions.

Key words building blocks, pentafluorosulfanyl group, sulfoximine, organofluorine compounds, sulfilmine

Fluorine-containing compounds exhibit unique physicochemical properties and, consequently, they are of interest in medicinal chemistry, crop protection, and material sciences.1 In this context, the pentafluorosulfanyl group (SF₅), also known as ‘super-trifluoromethyl’ group, plays a very special role.1,2 Noteworthy are, for example, the high thermal stability of aryl sulfurpentafluorides and the chemical inertness of the SF₅ group towards hydrolysis.3 Compared with a trifluoromethyl substituent, the SF₅ group has a higher electronegativity4 and polarity, and the respective molecules show improved lipophilicity.5 As a result, the SF₅ group has become an attractive structural motif in the design of biologically active compounds,2b,c,6 functional materials,7 and, as recently reported, in Brønsted acid catalysts.8

Due to the fact that only a few efficient synthetic methods for the introduction of the SF₅ group exist,3,8 commercially available SF₅-containing building blocks are rare and most of them are expensive. Therefore, the development of new scaffolds with SF₅ groups appears to be desirable.

Sulfoximines, the mono-aza analogues of sulfones, are widely used in asymmetric synthesis and catalysis.10 Especially in the last years, such compounds have also attracted attention as drugs11 and crop protection agents.12 Advantageously, in contrast to sulfones, they are modifiable at the sulfoximine nitrogen, which can lead to beneficial effects on the solubility of the respective molecules.13 Fluorine-containing sulfoximines11,12,14–16 are of particular interest because they combine the advantages of the sulfoximidoyl moiety with the favorable electronic and steric properties induced by, for example, a fluoro or a trifluoromethyl substituent. However, to our knowledge, sulfoximines bearing SF₅ groups are unprecedented. Here, we fill this synthetic gap and report on preparative routes towards a range of key compounds with sulfoximidoyl cores and SF₅ substituents.

For the preparation of the first target molecule (NH-sulfoximine 4), methyl 4-pentafluorosulfanylphenyl sulfide (1) was regarded as a promising starting material.17 Fulfilling our expectations, the imination of 1 with cyanamide and N-bromosuccinimide (NBS)18 proceeded smoothly, affording the corresponding N-cyano sulfilimine 2 in 96% yield (Scheme 1). Subsequent oxidation with m-CPBA18 led to N-cyano sulfoximine 3 in 81% yield. Finally, the CN-group was cleaved upon treatment with 50% aq. H₂SO₄ at 110 °C,19 providing the desired NH-sulfoximine 4 in 71% yield.20 Both enantiomers of the racemic mixture could be separated on analytical CSP HPLC, which allowed 4 to be obtained in non-racemic form by preparative HPLC separation.21

Considering that N-arylated sulfoximines can be highly selective ligands in asymmetric metal catalysis,10,22 we first investigated the application of a representative N-phenylsulfonyl-β-glucopyranosiose protocol allowing the conversion of 4-pentafluorosulfanylphenyl sulfoximine (4) into N-arylated sulfoximine 5 under copper catalysis.23 To our delight, this approach was
highly efficient, providing N-phenyl sulfoximine 5 in 93% yield starting from 4 and iodobenzene as aryl source (Scheme 2).

We then focused on the N-methylation of 4 to give 6. This transformation was regarded as particularly important because it was recently demonstrated that several N-methyl sulfoximines showed a significantly higher solubility compared with their isopropylidene counterparts in the sulfone series, leading to beneficial effects in their respective bioactivity studies. Here, the N-methylation of 4 was successfully performed under Eschweiler–Clark conditions, affording N-methylated sulfoximine 6 in 78% yield (Scheme 2).

Considering that tetrazoles are carboxylic acid bioisosteres that often exhibit high bioactivities, the conversion of N-cyano sulfoximine 3 into tetrazole 7 was studied.

By using a combination of NaN₃ and ZnBr₂ in methanol–water, formation of the heterocycle proceeded smoothly, leading to N-(1H)-tetrazole methyl 4-pentafluorosulfonylphenyl sulfoximine (7) in 62% yield (Scheme 2).

The three representative synthetic transformations depicted in Scheme 2 allow us to draw two significant conclusions: first, compounds such as 4 are readily available; and second, standard protocols can be used for modifications of sulfoximines with 4-pentafluorosulfonyl substituents providing interesting new building blocks for future synthetic and biological applications.

Synthesis of NH-Sulfoximine 4 from Sulfide 1; General Procedure: Step 1: To a solution of 1 (1.0 mmol) in MeOH (6 mL), was added NH₄CN (76 mg, 1.8 mmol), t-BuOK (191 mg, 1.7 mmol) and NBS (356 mg, 2.0 mmol). The reaction was stirred at room temperature until the starting material was consumed (reaction monitored by TLC). After removing the solvent under reduced pressure, water (10 mL) was added and the mixture was extracted with CH₂Cl₂ (3 × 20 mL). The combined organic layers were dried over anhydrous magnesium sulfate and the solvents were removed under reduced pressure. Purification by flash column chromatography provided N-cyanosulfilimine 2. Step 2: To a solution of 2 (0.3 mmol) in EtOH (2.7 mL) was added m-CPBA (ca. 70%, 101 mg, 0.45 mmol). The reaction mixture was stirred at room temperature until the starting material was consumed (reaction monitored by TLC). After removing the solvent under reduced pressure, H₂O (5 mL) was added and the mixture was extracted with CH₂Cl₂ (3 × 10 mL). The combined organic layers were dried over anhydrous magnesium sulfate and the solvents were removed under reduced pressure. Purification by flash column chromatography provided N-cyanosulfoximine 3. Step 3: A solution of 3 (0.23 mmol) in 50% aq. H₂SO₄ (2.3 mL) was stirred at 110 °C for 2 h. After cooling to room temperature and adjusting the pH to 9 by addition of aq. sat NaHCO₃ and aq. sat NaOH solution, the mixture was extracted with CH₂Cl₂ (3 × 20 mL). The combined organic layers were dried over anhydrous magnesium sulfate and the solvents were removed under reduced pressure. Purification by flash column chromatography provided NH-sulfoximine 4.
