Ruscogenin Protects against High-Fat Diet-Induced Nonalcoholic Steatohepatitis in Hamsters

Abstract
The protective effects of ruscogenin on nonalcoholic steatohepatitis in hamsters fed a high-fat diet were investigated. Ruscogenin (0.3, 1.0, or 3.0 mg/kg/day) was orally administered by gavage once daily for eight weeks. A high-fat diet induced increases in plasma levels of total cholesterol, triglycerides, and free fatty acids, while the degree of insulin resistance was lowered by ruscogenin. High-fat diet-induced hepatic steatosis and necroinflammation were improved by ruscogenin. Gene expression of inflammatory cytokines and activity of nuclear transcription factor-κB were also increased in the high-fat diet group, which were attenuated by ruscogenin. Ruscogenin decreased hepatic mRNA levels of sterol regulatory element-binding protein-1c and its lipogenic target genes. The hepatic mRNA expression of peroxisome proliferator-activated receptor α, together with its target genes responsible for fatty acid β-oxidation were upregulated by ruscogenin. In conclusion, these findings suggest that ruscogenin may attenuate high-fat diet-induced steatohepatitis through anti-inflammatory mechanisms, reducing hepatic lipogenic gene expression, and upregulating proteins in the fatty acid oxidation process.

Introduction
Nonalcoholic fatty liver disease (NAFLD) is defined as the accumulation of liver fat exceeding 5% of hepatocytes in the absence of significant alcohol intake (significant alcohol intake being defined as 20 g/10 g per day for men/women, respectively) or other specific etiology [1]. Nonalcoholic steatohepatitis (NASH), the extreme form of NAFLD, is characterized by an increase in fat deposition, fibrosis, oxidative stress, and chronic inflammation in the liver [2]. It is also a common cause of cirrhosis and could later progress to hepatocellular carcinoma [3]. A “multi-hit” theory has been proposed to depict the key pathogenic processes of NASH development. In this theory, obesity and insulin resistance is thought to be the “first hit” to the liver because it induces a net accumulation of lipid in hepatocytes which may cause the occurrence of following “hits”, such as oxidative stress, inflammation, fibrosis, and apoptosis [4]. Therapies that limit hepatic injury and the related occurrence of inflammation and fibrosis are particularly appealing for this condition. Ruscogenin [(1β,3β,25R)-spirost-5-en-1,3-diol; Fig. 1], first isolated from Ruscus aculeatus, is also a major steroidal sapogenin of the traditional Chinese herb Radix Ophiopogon japonicus, which has been clinically used for a long time to treat acute and chronic inflammatory and cardiovascular diseases [5]. In Chinese medicine, Radix Ophiopogon japonicus is the cardinal herb for yin deficiency. According to the Chinese Herbal Medicine Materia Medica, the herb is sweet, slightly bitter and slightly cold, enters the heart, lungs and stomach channels, and nourishes the yin of the stomach, spleen, heart and lungs, clears heat, and quiets irritability [6]. Ruscogenin acts as an elastase inhibitor, decreases capillary permeability, and is widely used to treat chronic venous insufficiency and vasculitis [7,8]. It has been previously found to exert significant antithrombotic activity, and the possible mechanism of ruscogenin could be attributed to its inhibition of intercellular adhesion molecule-1 upregulation via nuclear factor (NF)-κB p65 translocation induced by tumor necrosis factor (TNF)-α [9,10]. It was also found that ruscogenin significantly attenuated lipopolysaccharide-induced acute lung injury in a model with mice, which was possibly linked to the inhibition of NF-κB activation [11]. Such activities of ruscogenin indicate its potential protec-
tion in NAFLD/NASH-induced hepatic injury; however, there is no report about it until now. The present study was designed to explore the effects of ruscogenin in treating high-fat diet (HFD)-induced steatohepatitis and its possible mechanisms.

Results

At the end of eight weeks of treatment, the body weight, visceral fat, and relative liver weights in HFD-fed hamsters were significantly higher than those in the normal diet (ND)-fed group (Table 1). High doses of ruscogenin (3.0 mg/kg/day) suppressed body weight gain. The relative weights of the liver, epididymal adipose tissue, and perirenal adipose tissue were significantly lower in ruscogenin (3.0 mg/kg/day)-supplemented groups than those in the HFD-fed group (Table 1). Similar results were seen in HFD-fed hamsters treated with fenofibrate (Table 1). No significant differences in daily food or water intake were observed between the groups over the experimental period (Table 1). Plasma alanine aminotransferase (ALT) and aspartate aminotransferase (AST) activities in HFD-fed hamsters were higher than those in the ND-fed group (Table 1). The ALT and AST activities were markedly reduced in HFD-fed hamsters treated for eight weeks with a high dose (3.0 mg/kg/day) of ruscogenin (Table 1). The HFD caused elevated concentrations of plasma total cholesterol (TC), triglycerides (TG), and low-density lipoprotein cholesterol (LDL-C). Oral administration of ruscogenin at a dose of 0.3, 1.0, or 3.0 mg/kg/day significantly reduced plasma TC levels (22.8%, 31.4%, and 39.7% reduction, respectively) compared to that of vehicle-treated HFD-fed hamsters (Fig. 2A). All doses of ruscogenin decreased plasma TG levels in HFD-fed hamsters; the reduction of plasma TG induced by ruscogenin at 3.0 mg/kg/day was nearly 32.1% (Fig. 2A). Ruscogenin at an oral dose of 0.3, 1.0, or 3.0 mg/kg/day significantly reduced total plasma LDL-C levels (32.1%, 42.2%, and 52.8% reduction, respectively) compared to that of vehicle-treated HFD-fed hamsters (Fig. 2A). Plasma TC, TG, and LDL-C concentrations were reduced significantly by 46.7%, 37.8%, and 60.4%, respectively, in fenofibrate-treated HFD-fed hamsters compared with vehicle-treated HFD-fed hamsters (Fig. 2A).

The plasma concentration of high-density lipoprotein cholesterol (HDL-C) in HFD-fed hamsters was reduced to 60.4% of the level observed in the ND-fed group (Fig. 2A). After eight weeks of treatment with ruscogenin (3.0 mg/kg/day) or fenofibrate, the plasma HDL-C concentration in HFD-fed hamsters was elevated to nearly that of the ND-fed group (Fig. 2A). Plasma free fatty acid (FFA) levels in vehicle-treated HFD-fed hamsters were about 2.0-fold of that observed in the ND-fed group (Fig. 2A). The plasma FFA levels decreased by 38.1% in HFD-fed hamsters treated with ruscogenin (3.0 mg/kg/day) or fenofibrate, the plasma FFA levels decreased by 38.3% compared to their vehicle-treated counterparts (Fig. 2A). Fenofibrate treatment reduced FFA concentrations in HFD-fed hamsters by 38.3% relative to the level in vehicle-treated HFD-fed hamsters (Fig. 2A). The hepatic TC level was significantly higher in HFD-fed hamsters than in hamsters from the ND-fed group, which was reduced by 37.2% in HFD-fed hamsters treated with ruscogenin (3.0 mg/kg/day; Fig. 2B). Ruscogenin treatment (3.0 mg/kg/day) also produced a significant reduction in the hepatic TG concentration by 27.2% of that in the vehicle-treated HFD-fed hamsters (Fig. 2B). Hepatic TC and TG levels were significantly reduced (by 44.5%...

The vehicle (distilled water) used to prepare the tested medication solution was given at the same volume. Values (mean ± S.D.) were obtained from each group of eight animals after eight weeks of the experimental period. *P < 0.05 and **P < 0.01 compared to vehicle-treated ND-fed hamsters in each group, respectively. *P < 0.05 and **P < 0.01 compared to vehicle-treated HFD-fed hamsters in each group, respectively.
and 35.5%, respectively) in fenofibrate-treated HFD-fed hamsters compared with their vehicle-treated counterparts (Fig. 2B).
The hepatic FFA levels were significantly increased in hamsters fed an HFD, which were decreased by 37.3% and 41.2% in HFD-fed hamsters treated with ruscogenin (3.0 mg/kg/day) and fenofibrate, respectively (Fig. 2B).

Representative histological photomicrographs of liver specimens are shown in Fig. 3. Hamsters fed a ND had normal liver histological findings; however, numerous macrovascular fat droplets and mild necroinflammatory foci were present in the livers of those fed an HFD. The treatment of HFD-fed hamsters with ruscogenin (3.0 mg/kg/day) and fenofibrate, respectively, significantly downregulated the hepatic levels of MCP-1, TNF-α, and IL-6 to 51.1%, 63.3%, and 53.3%, respectively, compared with those in the vehicle-treated counterparts (Fig. 5). Fenofibrate treatment reversed the HFD-induced increase of hepatic levels of MCP-1, TNF-α, and IL-6 to 36.1%, 57.0%, and 44.9%, respectively, compared with their vehicle-treated counterparts (Fig. 5).

Fig. 2 Changes of lipid profile and FFA in plasma (A) and livers (B) of ND- or HFD-fed hamsters receiving eight weeks of treatments. HFD-fed hamsters were dosed by oral gavage once daily for eight weeks with 0.3 mg/kg ruscogenin (RUS 0.3), 1.0 mg/kg RUS (RUS 1), 3.0 mg/kg RUS (RUS 3), or 100 mg/kg fenofibrate (FENO). ND- or HFD-fed hamsters receiving vehicle treatment were administered the same volume of vehicle (VEH) used to prepare test medications. Data are expressed as the mean with S.D. (n = 8 per group) in each column. " P < 0.01 and " p < 0.01 compared to vehicle-treated ND-fed hamsters in each group, respectively. " P < 0.05 and " p < 0.01 compared to the values of vehicle-treated HFD-fed hamsters in each group, respectively.
An HFD significantly increased NF-κB activity (by 3.2-fold relative to that of the vehicle-treated ND-fed group) in the livers of hamsters (Fig. 6A). The HFD-induced upregulation of NF-κB activity was reduced 39.1% and 48.1% relative to that of the HFD-fed hamsters after eight weeks of treatment with ruscogenin (3.0 mg/kg/day) or fenofibrate, respectively (Fig. 6A). The phosphorylation degree of hepatic NF-κB in HFD-fed hamsters was also higher by 2.5-fold relative to their vehicle-treated

There were eight animals in each group. Data are expressed as the number of hamsters exhibiting the grade of steatosis or necroinflammation indicated.

Lu H-J et al. Ruscogenin Protects against... Planta Med 2014; 80: 870–879

This document was downloaded for personal use only. Unauthorized distribution is strictly prohibited.
counterparts (Fig. 6B). Treatment for eight weeks with rusco- 
genin (3.0 mg/kg/day) or fenofibrate decreased phosphorylated 
NF-κB in the livers of HFD-fed hamsters to 59.3% and 49.1%, re- 
spectively, relative to the vehicle-treated controls (Fig. 6 B).

An HFD markedly increased the hepatic mRNA levels of sterol 
regulatory element-binding protein (SREBP)-1c in hamsters 3.2- 
fold relative to those in the ND-fed group (Fig. 7 A). Ruscogenin 
(3.0 mg/kg/day) suppressed the HFD-induced stimulation in he- 

patic mRNA levels of SREBP-1c to 63.5% relative to those in the 
vehicle-treated group (Fig. 7A). Hepatic mRNA levels of 
SREBP-1c were reduced (by 46.9%) in fenofibrate-treated 
HFD-fed hamsters compared with their vehicle-treated counter-
parts (Fig. 7A).

An HFD caused a 2.8-fold induction of hepatic acetyl-CoA carbox-
ylase (ACC) mRNA and a 2.5-fold induction of hepatic fatty acid 
synthase (FAS) mRNA relative to those in the ND-fed group. The 
hepatic mRNA levels of ACC and FAS were downregulated by rus-
cogenin (3.0 mg/kg/day) treatment, with a decrease of 23.5% and 
36.7%, respectively, when compared with those observed in the 
vehicle-treated group (Fig. 7 A).

The mRNA levels of peroxisome proliferator-activated receptor 
(PPAR)α in the livers of HFD-fed hamsters were lowered to 
55.1% compared with those from the ND-fed group (Fig. 7 B).

HFD-fed hamsters administered ruscogenin (3.0 mg/kg/day) or 
fenofibrate for eight weeks upregulated the hepatic PPARα mRNA 
levels to 1.6- and 1.7-fold relative to those in the vehicle-treated 
group, respectively (Fig. 7 B).

Compared with the ND-fed group, the hepatic mRNA levels of 
carnitine palmitoyl transferase (CPT)-1 and acyl-CoA oxidase 
(ACO) in HFD-fed hamsters decreased obviously, and were upre-
gulated by fenofibrate treatment (a 1.9- and 2.3-fold increase, re-
spectively). The hepatic mRNA levels of CPT-1 and ACO in 
HFD-fed hamsters receiving ruscogenin (3.0 mg/kg/day) supple- 
mentation were increased 1.6- and 2.0-fold relative to the ex-
pression levels in their vehicle-treated counterparts, respectively (Fig. 7 B).
In our model, HFD-fed hamsters developed hepatic steatosis, visceral obesity, hyperlipidemia, and increased FFA and HOMA-IR values, mimicking almost all of the clinical features of human NAFLD [12]. Fenofibrate, a fibric acid derivative, is a commercially available drug in the management of hyperlipidemia and NAFLD [13]. Fenofibrate was used to compare the efficacy of ruscogenin.

Similar to the effects of fenofibrate, we found that ruscogenin supplementation significantly decreased body and liver weights, and plasma and liver contents of TG, TC, and FFA. In addition, ruscogenin attenuated the development of HFD-induced hepatic steatosis and injury as assessed by microscopic analysis. These data demonstrated that ruscogenin shows biological activity towards the regulation of lipid metabolism and steatosis development in the liver.

As inflammation plays a pivotal role in NAFLD, its modulation represents an important pharmacological target of inflammatory activation [14]. We therefore investigated whether ruscogenin could improve fatty liver changes by decreasing inflammatory cytokines in the HFD-induced NAFLD hamsters. Administration of ruscogenin during NAFLD development significantly attenuated the expression of MCP-1, TNF-α, and IL-6 in the liver of HFD-fed hamsters. These data indicate that ruscogenin might be effective for preventing and reversing the inflammatory response, which may accelerate the lipid metabolism disorder and/or more severe liver injuries. Actually, these inflammatory cytokines are shown to be involved in the development of insulin resistance [15].

Discussion

In our model, HFD-fed hamsters developed hepatic steatosis, visceral obesity, hyperlipidemia, and increased FFA and HOMA-IR values, mimicking almost all of the clinical features of human NAFLD [12]. Fenofibrate, a fibric acid derivative, is a commercially available drug in the management of hyperlipidemia and NAFLD [13]. Fenofibrate was used to compare the efficacy of ruscogenin. Similar to the effects of fenofibrate, we found that ruscogenin supplementation significantly decreased body and liver weights, and plasma and liver contents of TG, TC, and FFA. In addition, ruscogenin attenuated the development of HFD-induced hepatic steatosis and injury as assessed by microscopic analysis. These data demonstrated that ruscogenin shows biological activity towards the regulation of lipid metabolism and steatosis development in the liver.

As inflammation plays a pivotal role in NAFLD, its modulation represents an important pharmacological target of inflammatory activation [14]. We therefore investigated whether ruscogenin could improve fatty liver changes by decreasing inflammatory cytokines in the HFD-induced NAFLD hamsters. Administration of ruscogenin during NAFLD development significantly attenuated the expression of MCP-1, TNF-α, and IL-6 in the liver of HFD-fed hamsters. These data indicate that ruscogenin might be effective for preventing and reversing the inflammatory response, which may accelerate the lipid metabolism disorder and/or more severe liver injuries. Actually, these inflammatory cytokines are shown to be involved in the development of insulin resistance [15].

Lu H-J et al. Ruscogenin Protects against ... Planta Med 2014; 80: 870–879
observed that not only hyperinsulinemia but also higher HO-
MA-IR values were alleviated by ruscogenin treatment in
HFD-fed hamsters. These results further suggest that ruscogenin
could ameliorate fatty liver in the insulin-resistant state.
NF-κB is a ubiquitous and well-known transcription factor, which
undergoes phosphorylation on serine 276 in its p65 subunit and
associates with surrounding chromatin components. It subse-
quently binds with DNA and promotes the transcription of proin-
flammatory cytokines, chemokines, and adhesion molecules
[16]. Thus, detection of the phosphorylated p65 subunit of NF-
κB was effective for evaluating NF-κB activation [17]. Ruscogenin
has been reported to have anti-inflammatory activity through in-
hibiting NF-κB activity [10, 11]. The inhibition of NF-κB by rusco-
genin might be a critical step for prevention of the cascading in-
flammatory response during NAFLD development. In the present
study, ruscogenin significantly inhibited hepatic NF-κB activation
in HFD-fed hamsters, as evidenced by a decrease in NF-κB activity
and downregulation of phosphorylated NF-κB. These results sug-
gest that ruscogenin inhibits the activation of NF-κB, leading to
the downregulation of inflammatory mediators and, therefore,
shows a promising effect in preventing NAFLD. Whether rusco-
genin can directly target NF-κB or act as the upstream signaling
molecules for its activation requires further investigation.
To explore the possible mechanisms whereby ruscogenin de-
creases hepatic lipid accumulation, we then investigated the ex-
pression levels of several genes related to lipid metabolism, in-
cluding lipogenesis and β-oxidation. SREBP-1c has been shown to
regulate the transcription of genes in the lipogenic pathway in-
cluding ACC and FAS [17]. Liver-specific ACC knockout mice
showed a decreased hepatic triglyceride accumulation, suggest-
ning that ACC plays a crucial role in the regulation of lipogenesis
[18]. FAS catalyzes the last step in fatty acid biosynthesis and is
thus believed to be a major determinant of the maximal hepatic
capacity to generate fatty acids by de novo lipogenesis [19]. Low
levels of SREBP-1c mRNA in the livers of HFD-fed hamsters re-
ceiving ruscogenin were accompanied by a concomitant reduc-
tion in the expression of ACC and FAS mRNA. Ruscogenin is thus
likely to have an inhibitory effect on SREBP-1c expression, which
in turn decreases transcription of its target lipogenic genes,
thereby reducing enzyme activity and resulting in a low rate of
lipid synthesis. Ruscogenin appeared to mediate its beneficial ef-
fects on HFD-induced hepatic steatosis by downregulating ex-
pression of hepatic genes related to lipid synthesis.
PPARα mediates β-oxidation of fatty acids, and agonists of PPARα
possess the property of reducing lipid dystrophy and obesity
[20]. PPARα activates some of the key enzymes of β-oxidation
and β-oxidation of fatty acids in the liver [21]. HFD-fed hamsters
displayed a reduced expression of PPARα in the liver. A multitude
of studies have postulated that during diet-induced obesity, fatty
acid oxidation is left incomplete accompanied by mitochondrial
lipid overload and dysfunction. To explore whether the effect of
ruscogenin on the attenuation of HFD-induced hepatic steatosis
was related to the PPARα-mediated pathway, mRNA expression
of PPARα and its target genes responsible for β-oxidation of fatty
acids was measured. Ruscogenin markedly increased the HFD-in-
duced low expression of hepatic PPARα mRNA. Furthermore, rusco-
genin treatment upregulated the PPARα-mediated transcription
of CPT-1 and ACO mRNA in the liver of HFD-fed hamsters.
CPT-1 and ACO are major enzymes that catalyze fatty acid β-oxi-
dation and are responsive to PPARα activation [22, 23]. The simi-
lar trend in expression among these genes suggests that rusco-
genin enhanced β-oxidation of fatty acids via the pathway involving
PPARα-mediated gene transcription.
ALT and AST are considered to be sensitive indicators of hepat-
cellular damage and, within limits, can provide a quantitative
evaluation of the degree of damage to the liver [24]. We found
that the ALT and AST activities were markedly reduced in
HFD-fed hamsters treated for eight weeks with ruscogenin. It
seems that animals treated with ruscogenin at the chosen doses
exhibited no evidence of hepatotoxicity. For a more reliable
safety evaluation performed on the basis of the acceptable daily
intake concept, data on the chronic toxicity, reproductive toxicity,
genotoxicity, and carcinogenicity of ruscogenin would also be
required.
In conclusion, the results of this study demonstrated that rusco-
genin exerted a protective effect on HFD-induced hepatic steato-
sis in hamsters by modulating lipid metabolism-associated
genomes. It is also possible that the inhibition of NF-κB activation
thereby led to the downregulation of inflammatory mediators
and this is integral to the protective functions of ruscogenin in
HFD-induced hepatocellular injury and its subsequent progres-
sion to steatohepatitis.

Materials and Methods

Animal models
Male Golden Syrian hamsters, eight weeks old and weighing
90 ± 10 g, were obtained from the National Laboratory Animal
Center. They were maintained in a temperature-controlled room
(25 ± 1 °C) on a 12-h:12-h light–dark cycle (lights on at 06:00 h)
in our animal center. Food and water were provided ad libitum.
An ND (#D12450B, Research Diets) with 20 kcal% protein,
70 kcal% carbohydrate, and 10 kcal% fat from lard was used as
the maintenance and control diet. A purified ingredient HFD
with 20 kcal% protein, 35 kcal% carbohydrate, and 45 kcal% fat primarily
from lard (#D12451, Research Diets) was used to induce
weight gain [25]. All animal procedures were performed accord-
ing to the Guide for the Care and Use of Laboratory Animals of
the National Institutes of Health, as well as the guidelines of the
Animal Welfare Act. These studies were conducted with the approval
of the Institutional Animal Care and Use Committee (IACUC) at
Tajen University (approval number, IACUC 101–16; approval
date, December 24, 2012).

Treatment protocols
After being fed an HFD for two weeks, hamsters were dosed by
oral gavage once per day for eight weeks with ruscogenin (doses of
0.3, 1.0 or 3.0 mg/kg) in a volume of 1.5 ml/kg distilled water.
The dosage regime was selected based on a previous report demon-
strating that ruscogenin (≥98%; Chengdu Biopurify Phyto-
chemicals Ltd.; Cat. No. 472–11–7) at the indicated dosage regi-
men was potentially effective in inhibiting inflammation in mice
[11]. Another group of HFD-fed hamsters was treated orally for
eight weeks with 100 mg/kg/day fenofibrate (isopropyl 2-[4-
(4-chlorobenzoyl)phenoxyl]–2-methylpropionate; Laboratories
Fournier SA) with a purity greater than 99.5%. Two g of powdered
fenofibrate was dissolved in 20 ml of distilled water, so that 1 ml
will contain 100 mg of fenofibrate. The dose of fenofibrate was
based on a study reporting that long-term fenofibrate treatment
could ameliorate hepatic insulin resistance and steatosis in high-
fructose-fed mice [26]. The control groups received water by ga-
vage instead of ruscogenin or fenofibrate. Water consumption,
food intake, and body weight were measured individually at the same time (09:00 h) on each day throughout the experiment. Food cups containing fresh food were weighed at the beginning and end of each 24-h period. Food intake was calculated by determining the difference in food cup weights, adjusting for any spillage that occurred. Water intake was calculated by measuring the difference in water bottle weights at the beginning and end of the daily change of water.

After eight weeks of treatment, animals were weighed and sacrificed by being deeply anesthetized with ketamine (50–75 mg/kg) after fasting for 12 hours. Blood samples were taken from the inferior vena cava for analysis. After blood collection, the left lobe of the liver, and visceral and subcutaneous white adipose tissue (WAT) were removed, rinsed with a physiological saline solution, and immediately stored at −80 °C in liquid nitrogen until assayed. The hepatic weight coefficient was also calculated as liver weight (g) divided by body weight (100 g). The right hepatic lobe was fixed in 10% neutralized formalin for histology.

**Determination of plasma biochemical parameters and insulin sensitivity**

Blood samples were centrifuged at 2000 × g for 10 min at 4 °C. The plasma was then removed and placed into aliquots for the respective analyses. Kits for determining plasma glucose (Cat. No. 10009582) concentration was purchased from Cayman Chemical Company. Commercial enzyme-linked immunosorbent assay (ELISA) kits were used to quantify plasma insulin concentration (LINCO Research, Inc.; Cat. # EZRMI-13K). Whole-body insulin sensitivity was estimated using HOMA-IR with the following formula: [fasting plasma glucose (mmol) × fasting plasma insulin (mU/mL)]/22.5 [27]. Diagnostic kits for determination of plasma levels of TC (Cat. # 10007640) and TG (Cat. # 10010303) were purchased from Cayman Chemical Company. The diagnostic kit for determination of plasma levels of HDL-C was purchased from Bio-Quant Diagnostics (Cat. # BQ 019CR). LDL-C concentrations in plasma were determined by a commercial ELISA kit (antibodies-online, Inc.; Cat. # ABIN416222). The plasma FFA level was determined using an FFA quantitation kit obtained from Abcam plc (Cat. # ab65341). Kits for determination of plasma ALT (EC 2.6.1.2) (Cat. No. A524-780TM) and AST (EC 2.6.1.1) (Cat. No. A559-780TM) concentrations were purchased from Tecno Diagnostics. All analyses were performed in triplicate in accordance with the manuals provided by the manufacturers.

**Measurement of hepatic lipids**

Liver tissue (0.5 g) was homogenized for 5 min in 1 mL of ice-cold phosphate-buffered saline (PBS) using a tissue homogenizer (Teflon Potter-Elvejhem tissue homogenizer in 10 mmol/L Tris-HCl buffered solution (pH 7.4) containing 2 mol/L NaCl, 1 mmol/L EDTA, 0.01% Tween 80, and 1 mmol/L PMSF, and centrifuged at 9000 × g for 30 min at 4 °C. The resultant supernatant was used for cytokine determination. ELISA kits for the determination of MCP-1 (Cat. No. ab100777), TNFα (Cat. No. ab46070), and IL-6 (Cat. No. ab100772) were obtained from Abcam, Inc. Samples were assayed in triplicate according to the manufacturer’s instructions. The protein concentrations of liver filtrate were determined using a Bio-Rad protein assay kit (Bio-Rad Laboratories) and bovine serum albumin (BSA) as a standard.

**Hepatic histology**

After the liver samples were fixed in 10% formalin solution at room temperature, they were processed by the standard method. Briefly, tissues were embedded in paraffin, sectioned at 5 µm, and stained with hematoxylin and eosin (H&E), and then picked up on glass slides for light microscopy. All samples were evaluated by an experienced pathologist who was blinded to the experiment. A semiquantitative scoring system was used to assess the severity of hepatic steatosis and necroinflammation in 10 microscopic fields examined at 200× magnification as described previously [28]. Steatosis was scored as the percentage of parenchymal cells containing fat: 0 = no parenchymal cells containing fat, 1 = < 20% of parenchymal cells containing fat, 2 = 20–39% of parenchymal cells containing fat, 3 = 40–50% of parenchymal cells containing fat, and 4 = > 51% of parenchymal cells containing fat. Inflammation and necrosis were scored by the number of foci of inflammation and necrosis identified under a low-power field of a light microscope: 0 = no inflammation and necrosis, 1 = 1 foci of inflammation and necrosis per low-power field, 2 = 2 foci of inflammation and necrosis per low-power field, and 3 = 3 foci of inflammation and necrosis per low-power field.

**Nuclear transcription factor-κB activity measurement**

Nuclear extracts of livers from the above-mentioned groups were prepared using the nuclear extraction kit (Active Motif; Cat. No. 40010). In brief, the liver (0.5 g) was pulverized under liquid nitrogen. Powdered tissue was suspended in hypotonic buffer containing a protease inhibitor cocktail, phosphatase inhibitors, DTT, and detergent (Active Motif). Samples were dounce homogenized, incubated on ice for 15 min, and then centrifuged (850 × g, 10 min, 4 °C). The pellet was suspended in hypotonic buffer containing detergent and then centrifuged (14000 × g, 30 s, 4 °C). The resulting pellet was suspended in lysis buffer and incubated on ice for 30 min, and then nuclear extracts were obtained by centrifugation (14000 × g, 10 min, 4 °C). Twenty micrograms of nuclear extract were used for the determination of NF-κB activity with the TransAM® NF-κB p65 transcription factor assay kit (Active Motif; Cat. No. 40096), according to the manufacturer’s instruction.

**Western blotting**

Liver tissues were homogenized in 1 mL of ice-cold hypotonic buffer A [10 mmol/L HEPES (pH 7.8), 10 mmol/L KCl, 2 mmol/L MgCl2, 1 mmol/L DTT, 0.1 mmol/L EDTA, 0.1 mmol/L phenylmethanesulfonylfluoride]. The cell homogenate was centrifuged and the supernatant containing the cytoplasmic extracts was stored frozen at −80 °C. The nuclear pellet was resuspended in 25 µL ice-cold nuclear extraction buffer. After 30 min of intermittent mixing, the extract was centrifuged, and the supernatants containing nuclear extracts were secured. Before immunoblotting, the protein concentration of each tissue was determined using a Bio-Rad protein assay kit (Bio-Rad Labo-
Analysis of mRNA expression of hepatic genes

Total RNA was extracted from 100 mg frozen liver samples using Trizol reagent (Invitrogen). RNA was quantified by Agilent 2100 and its integrity verified by agarose gel electrophoresis using ethidium bromide for visualization. For the reverse transcriptase reaction, 1 μg of total RNA per sample and 8.5 μg/μL random hexamer primers were mixed at 65°C for 5 min and then quenched on ice. This mixture was combined with 500 μmol/L each of dATP, dGTP, dCTP, and dTTP, 10 mmol/L DTT, 20 mmol/L Tris–HCl (pH 8.4), 50 mmol/L KCl, 5 mmol/L MgCl2, 40 units of RNaseOUT™ recombinant ribonuclease inhibitor (Invitrogen), and 100 units SuperScript III reverse transcriptase (Invitrogen). Samples were subjected to DNase (Promega) treatment at 37°C for 20 min in a GeneAmp 9700 Thermal Cycler (Applied Biosystems) and then held at 4°C. After the aliquots were taken for immediate use in PCR, the remainder of the cDNA was stored at −20°C. mRNA expression was measured by real-time quantitative reverse transcription polymerase chain reaction (RT-PCR) in a fluorescent temperature Lightcycler 480 (Roche Diagnostics). The following primer sequences were used: 5’-TCAACAACAAAGACAGTGACTCTCCTGGCC-3’ (forward) and 5’-GTTCTCTGCTTTGAGCCTCCTGTGGTCTG-3’ (reverse) for SREBP-1c; 5’-GAGGCTACCAAGCTGTGAGTTTGTG-3’ (forward) and 5’-CATGGTCTACACAGGACG-3’ (reverse) for CPT-1; 5’-ACTATATTTGCGGTTTTGTTGC-3’ (forward) and 5’-TGGTATGCATTGCTTTACACCCC-3’ (reverse) for ACOD; 5’-TACATATTTGCGGTTTTGTTGC-3’ (forward) and 5’-TGGTATGCATTGCTTTACACCCC-3’ (reverse) for ACOD; 5’-TACATATTTGCGGTTTTGTTGC-3’ (forward) and 5’-TGGTATGCATTGCTTTACACCCC-3’ (reverse) for ACOD; 5’-TACATATTTGCGGTTTTGTTGC-3’ (forward) and 5’-TGGTATGCATTGCTTTACACCCC-3’ (reverse) for ACOD; 5’-TACATATTTGCGGTTTTGTTGC-3’ (forward) and 5’-TGGTATGCATTGCTTTACACCCC-3’ (reverse) for ACOD.
