Mechanisms of Action of Phytochemicals from Medicinal Herbs in the Treatment of Alzheimer’s Disease

Abstract

Alzheimer’s disease is a chronic neurodegenerative disorder characterized by progressive dementia and deterioration of cognitive function. Although several drugs currently used for the treatment of Alzheimer’s disease delay its onset and slow its progression, still there is no drug with profound disease-modifying effects. Studies aiming the treatment of this neurodegenerative disorder explore various disease mechanisms. Since antiquity, medicinal herbs have been used in traditional medicine. Recent studies suggest that the neurobiological effects of phytochemicals from medicinal herbs may contribute to clinical benefits in in vitro and in vivo models of Alzheimer’s disease. This review focuses on five phytochemicals, berberine, curcumin, ginsenoside Rg1, puerarin, and silibinin, which have been mostly investigated to treat the development and progression of this neurodegenerative disorder.

Abbreviations

AchE: acetylcholinesterase
AD: Alzheimer’s disease
Akt: protein kinase B
Aβ: β-amyloid
APP: amyloid precursor protein
BACE: β-secretase or beta-site amyloid precursor protein cleaving enzyme
Bax: Bcl-2-associated X protein
Bcl-2: B-cell leukemia protein
BDNF: brain-derived neurotrophic factor
CAT: catalase
Cox: cyclooxygenase
CTF: C terminal fragment
Cyt c: cytochrome c
ELISA: enzyme-linked immunosorbent assay
FDA: Food and Drug Administration
γ-GCS: γ-glutamylcysteine
GFAP: glial fibrillary acidic protein
GRg1: ginsenoside Rg1
GSH-Px: glutathione peroxidase
GSK3β: glycogen synthase kinase
Iba-1: ionized calcium binding adaptor molecule-1
IL: interleukin
i-Nos: inducible nitric oxide synthase
JNK: c-Jun N-terminal kinase
LDH: lactate dehydrogenase
MAP-2: microtubule-associated protein
MAPK: mitogen-activated protein kinase signaling
MAPK-2: microtubule-associated protein (MAP)-2
MCP-1: monocyte chemoattractant protein-1
MDA: malondialdehyde
MWM task: Morris water maze task
NF-κB: nuclear factor-κB
NICE: National Institute for Health and Clinical Excellence
NO: nitric oxide
p-ERK1/2: extracellular signal-regulated kinase 1 and 2
PI3K: phosphoinositide 3-kinase
PS1: presenilin 1
PTEN: phosphatase and tensin homolog
RAWM: radial arm water maze
RNS: reactive nitrogen species
ROS: reactive oxygen species
SYN: synaptophysin
TEM: transmission electron microscopy
ThT: thioflavin T
(TNF)-α: tumor necrosis factor-α
TUNEL: terminal deoxynucleotidyl transferase dUTP nick end labeling
Introduction

AD, a progressive irreversible neurodegenerative disorder characterized by the loss of certain cognitive functions, behavioral disturbances, and daily living difficulties, is the most common form of dementia found among elderly individuals [1]. This disease currently affects 27 million people all over the world [2]. The prevalence rate for AD has become the third greatest threat to the elderly, only behind cardiovascular disease and cancer [3]. Although neither a consensus concerning the pathogenesis of AD nor a perfect therapy for its treatment is available, it is now well accepted that multiple factors, including apoptosis, oxidative stress, excitotoxicity, and the disturbance of energy metabolism homeostasis, contribute to the progression of AD [4]. Especially, the aggregation and accumulation of extracellular and intracellular Aβ play a critical role in the pathogenesis of AD and result in impaired synaptic plasticity and memory [5]. As a key rate-limiting enzyme, α-, β-, and γ-site amyloid precursor protein cleaving enzyme (α-, β-, and γ-secretase) initiates the formation of Aβ by producing the peptide from APP [6]. APP can be cleaved in two ways, with formation of non-toxic Aβ1-42 by α- and γ-secretases and the generation of toxic Aβ1-40 by β- and γ-secretases [7]. Therefore, inhibiting the activity of β-secretases is important for treating AD due to their role in the direct cleavage of the Aβ domain at the N-terminus in APP [8]. These changes are closely associated with tau phosphorylation and PI3K/Akt/GSK3β signaling pathway along with MAPK signaling. The Akt-mediated control of GSK3β activity is involved in tau hyperphosphorylation [9]. Aβ generated by the cleavage of APP triggers immune responses and activates microglial cells that engulf Aβ filaments, with secretion of various pro-inflammatory factors [9, 10]. In addition, neuron-related apoptosis and oxidative stress lead to neuronal damage [11].

Numerous in vitro and in vivo models have been used for studying AD. Various types of cells were stimulated with neurodegenerative exposures such as to subtypes of Aβ and acrolein. Aβ deposition causes synaptic plasticity and memory impairment and has been detected in AD patients at early stage [12]. Acrolein is not only a marker of lipid peroxidation but also an inducer of oxidative stress and an effecter of tissue damage [13]. With growing evidence of the implication of acrolein in AD, the development of strategies to reduce its toxic effect is of great importance [12].

Cognitive impairments in animal models are analyzed with behavioral tests, such as MWM task and Y-maze, RAWM, novel object recognition as well as cued and contextual fear-conditioning tests, which are known to be sensitive to hippocampal-dependent learning and memory deficits. Specifically, TgCRND8 mice expressing human APP695 with the Swedish (K670N/M671L) and Indiana (V717F) mutations under regulatory control of the PrP gene promoter (heterozygous with respect to the transgene) on a C57BL/6 F3 background are used to breed the colony of experimental animals [14], while transgenic mouse overexpressing of APP/Aβ (Tg mAPP) is a well-used mouse model of AD [15, 16]. Despite great effort to discover a remedy for AD, no currently available drug can stop or cure this neurodegenerative disorder, and current treatments offer only small symptomatic benefits. The most commonly prescribed drugs are cholinesterase inhibitors such as donepezil, rivastigmine, and galantamine, and NMDA antagonists such as memantine. Though approved by the FDA, these drugs are not recommended by the NICE in England and Wales due to “limited and largely inconclusive” evidence concerning their efficacy [17]. Nootropic agents such as piracetam are commonly prescribed in Europe for the treatment of dementia, including dementia associated with AD, but there are insufficient evidences to verify the efficacy of such drugs [18].

Historically, a number of medicinal herbs have been used to treat neurodegenerative diseases and cognitive disorders in traditional European, Ayurvedic, and Oriental medicines. Medicinal herbs consist primarily of multiple compounds and may influence multiple mechanisms with multi-target functions. This review concerns five phytochemicals, berberine, curcumin, Grg1, puerarin, and silibinin, that have been recently and mostly investigated as alternative treatments for AD and will discuss the advances in our knowledge about these phytochemicals derived from medicinal herbs based on available literature facts collected from books and scientific papers by electronic search (PubMed, ScienceDirect, and Google Scholar) (Fig. 1).

Therapeutic Approaches to Alzheimer’s Disease

Berberine from the cortex of Coptis chinensis

Berberine, an isoquinoline alkaloid, is one of the major components of Cortex Phellodendri and Rhizoma Coptidis (Coptis chinensis, Franch.; Ranunculaceae). Berberine has been used in herbal medicine for liver disease, skin inflammation, diarrhea, and other disorders due to its anti-diarrheal, anti-microbial, and anti-inflammatory effects [8, 19–21]. Specifically, several studies have reported that berberine possesses multiple pharmacological effects that culminate in neuroprotective action against cerebral ischemia, psychological depression, schizophrenia, anxiety, and AD [22, 23]. Asai et al. reported that berberine reduces extracellular Aβ production and BACE activity without changes on release of LDH in H4 neuroglioma (APPNL-H4) cells [8]. The production of both Aβ and β-secretase are inhibited by berberine compared with the control in human embryonic kidney 293 (HEK293) cells. Berberine increased the expression level of p-ERK1/2, demonstrating that it may inhibit the production of Aβ via an activation of ERK1/2-induced BACE activity in HEK293 [24].

In another study, the effect of berberine on Aβ-induced neuroinflammation was examined in primary and BV2 microglial cells. Pretreatment with berberine reduces Aβ-induced IL-6 production and MCP-1 release, as well as expression of Cox-2 and inducible i-Nos. Subsequently, NF-κB and the phosphorylation of IkB-α, Akt, p38 kinase, and ERK1/2, but not JNK, stimulated by Aβ, are regulated following treatment with berberine [25]. Moreover, pretreatment with berberine reduced Aβ-stimulated activities of LDH and TNF-α with down-regulation of TNF receptor 1 in SK-N-SH neuroblastoma cells [26].

In APP transgenic mice, berberine treatment improved cognitive impairment as reflected in reductions in errors in the MWM task with respect to both conventional reference memory and memory retention (probe trial). Aβ plaque immunostaining in TgCRND8 mice was associated with reductions in both the number and the area of coronal sections of the cortex and hippocampus following treatment with berberine. Moreover, consistent with the indication that berberine treatment reduces the accumulation of total Aβ peptides in the brain, a significant reduction was found in the degree of microgliosis by Iba-1 burden and astrocytosis by GFAP burden. The mechanisms underlying the benefits of berberine on cognitive function and Aβ neuropathology in TgCRND8 mice were expressed for CTF, APP, and tau phosphorylation. An inhibition of PI3K/Akt/GSK3β activities in the TgCRND8 mouse brain...
influenced CTF and p-APP levels and led to a blockage of Aβ accumulation [27] (Table 1).

Curcumin from *Curcuma longa*

Curcumin, a hydrophobic polyphenol, is isolated from the rhizome of the herb *Curcuma longa* L. (Zingiberaceae). It is one of the active components of turmeric involved in antioxidant, anti-inflammatory, metal chelators, anti-amyloid, anti-tau, and neuroprotective activities [13]. In addition, curcumin has been reported to bind to Aβ and prevent aggregation [28] and protect against cell death, as indicated by increased cell viability and decreased TUNEL-positive cells in rat primary neuron cells infected by adeno-5 virus packaged with iAβ1-42. Curcumin treatment decreased ROS level and protected from intracellular Aβ toxicity [12]. It also inhibited the expression of ROS in acrolein-induced toxicity on SK-N-SH human neuroblastoma cell with increasing...
LDH release. Lipid peroxidation and oxidative stress by acrolein were protected by curcumin treatment. In addition, the expressions of γ-GCS synthetase and RNS levels, except GSH, were restored by treatment of curcumin. Other oxidative damage marker expressions, such as those of Nrf2, NF-κB, Sirt1, and Akt, were regulated under the presence of curcumin [13]. In other type of human neuroblastoma (SH-SY5Y cells), curcumin treatment decreased Aβ-induced calcium increase. The Aβ-induced calcium increase was inhibited by treatment with curcumin [29]. Xiong et al. reported that the production of Aβ40 and Aβ42 was decreased by treatment with curcumin [29]. Curcumin reduced the activation of PS1 in both mRNA and protein levels in APP-overexpressing cells. This change was accompanied with decreased GSK3β mRNA and protein levels [30].

Furthermore, curcumin has shown beneficial effects through hippocampal-dependent memory improvement. Treatment with curcumin improved the spontaneous alternation behavior as well as the recognition memory task in Aβ-infused rats. Concerning protection of cognitive impairment, a decrease in SYN levels was blocked and the phosphorylation of tau protein in rat hippocampus was decreased under the presence of curcumin. The production of TNF-α and IL-1β and activation of GFAP immunoreactivity were decreased in curcumin-treated hippocampus compared with non-treated samples. Additionally, BDNF concentration and the phosphorylation of Akt and GSK3β revealed an increase after curcumin treatment [31] (Table 2).

Ginsenoside Rg1 from *Panax notoginseng*  
GRG1, a major active component of *Panax notoginseng* (Burk.) F.H. Chen (Araliaceae), is used to treat central nervous system dysfunctions, especially those involving cognitive abilities such as learning and memory [32]. The activity of β-secretase was inhibited in a concentration-dependent manner and a dose-dependent reversal of Aβ-induced decreased cell viability was observed following treatment with GRG1 in PC12 cells. GRG1 appeared to prevent oxidative damage through inhibition of LDH efflux, NO production, ROS induction, and lipid peroxidation. Additionally, treatment with GRG1 blocked this Aβ-induced calcium increase. To confirm the influence of GRG1 on apoptosis, caspase-3 activity was investigated by measuring the proteolytic cleavage of the fluorogenic substrate Ac-DEVD-AMC. The Aβ-induced increase in caspase-3 activity was inhibited by treatment with GRG1 [33]. In addition, Li et al. reported that GRG1 displayed anti-Aβ neurotoxicity via p38 pathway activation in SK-N-SH neuroblastoma cells induced by Aβ-stimulated THP-1 supernatant. Pretreatment with GRG1 markedly decreased LDH leakage, indicating that Aβ-induced neuronal injury can be blocked by GRG1. Along with decreased tau phosphorylation, GRG1 treatment resulted in elevated IL-1β and decreased SYN, number of MAP-2 positive cells, and activation of p38 MAPK, which is associated with elevations of phosphorylated tau [34]. In terms of apoptosis, some reports also found that increased cytokine release, including IL-1β, IL-8, and TNF-α, was inhibited by GRG1 pretreatment in conjunction with an up-regulation of Bcl-2 and a down-regulation of Bax. This, in turn, resulted in an increase in the Bcl-2/Bax ratio as well as a reduction in the activation of caspase-3 [35].
In addition, GRg1-treated cortical neurons from C57BL/6 mouse fetuses with Aβ1-42 inhibited the expression of Cyt c in cytosolic fraction, whereas Cyt c levels in mitochondrial fractions were increased. Marked decrease in caspase-3 activity and TUNEL-positive apoptotic neurons were shown in GRg1-treated groups [36]. In cortical neurons from embryonic rat fetuses, GRg1 treatment protected Aβ25-35-induced cell death. Bcl-2/Bax ratio was increased with reduced caspase-9 and -3 activities by GRg1 treatment. Release Cyt c from mitochondria was blocked with GRg1 treatment [37]. Similarly, increased LDH release was suppressed against cytotoxicity of Aβ25-35 under the presence of GRg1. GRg1 reduced the numbers of apoptotic cells, as shown in decreased annexin V+/PI fraction. The ratio of Bcl-2/Bax was up-regulated and activation of caspase-3 was down-regulated by GRg1 treatment [38].

In an animal study, Fang et al. demonstrated the neuroprotective effects of GRg1 in transgenic AD mice. ELISA and immunostaining with an Aβ antibody revealed that Aβ plaque loads were lower in the cerebral cortex and hippocampus of GRg1-treated mAPP mice than in vehicle-treated mice. This lower accumulation of Aβ in the cortices of GRg1-treated mice stemmed from the inhibition of γ-secretase activity and did not affect levels of AChE-positive neurites in the entorhinal cortex. Compared with vehicle-treated mAPP mice, GRg1-treated mice were shown to improve their performance in RAWM task [39] (Table 3).

Puerarin from the radix of Pueraria lobata

Previous research has demonstrated that puerarin (from Pueraria lobata (Willd.) Ohwi.; Fabaceae), which has been widely used in traditional medicine for thousands of years, exhibits anti-oxidant, anti-myocardial, anti-ischemic retinopathy, and anti-hyperglycemic effects [40,41]. Zou et al. reported that puerarin have a protective effect against Aβ-induced neurotoxicity in rat hippocampal neurons via various mechanisms. Pretreatment with puerarin decreased Aβ-induced cell death in cultured rat hippocampal neurons by inhibiting GSK-3β via activation of Akt [42]. Furthermore, puerarin treatment resulted in an increase in GSH-Px and CAT activities and a decrease in the production of ROS [43].

In addition, treatment with puerarin prevented Aβ25-35-induced apoptosis, as a result of decrease of TUNEL-positive cells and annexin V+/PI fraction. Puerarin-treated cells inhibited the expression of caspase-3 with increased expression of Bcl-2 and decreased expression of Bax [44]. Similarly, Zhang et al. demon-

† Increase; ↓ decrease; ↔ no difference
strated that puerarin protected against cybrid viability loss in mitochondrial transgenic neuronal cells. Annexin V+/PI fraction and intracellular ROS levels were attenuated by puerarin treatment. In addition, the expression of Bax, Bcl-2, phosphorylation of GSK3β and Bad was increased, while the production of caspase-9 was decreased via activation of Akt. Furthermore, the phosphorylation of JNK and p38 were regulated by treatment of puerarin [45].

Another study found that puerarin treatment resulted in a significant enhancement of MWM task against Aβ [41]. In animal experiments, silibinin ameliorates Aβ-induced oxidative stress, levels of MDA and GSH were analyzed. Treatment with silibinin appeared to decrease MDA levels and increase GSH levels in the hippocampus [51]. The cued freezing response and contextual freezing response were attenuated in silibinin-treated animals, indicating an impairment in associative memory. However, silibinin did not change the level of response to electric foot shock (flinching, vocalization, and jumping) in either group. A significant increase in nitrotyrosine, TNF-α, and i-Nos levels in the hippocampus and amygdala were reduced following treatment with silibinin compared with distilled water [52] (Table 4).

Silibinin from the herb milk thistle (*Silybum marianum*)
Silibinin is a flavonoid derived from the herb milk thistle (*Silybum marianum* (L.) Gaertn.; Asteraceae) and is known to have anti-oxidative and anti-inflammatory properties [47]. Various studies have indicated that silibinin confers protection against oxidative stress in hepatocytes by decreasing lipid peroxidation, a sensitive marker of oxidative lipids and scavenging of free radicals [48,49]. Silibinin is protective against Aβ-induced oxidative stress in SH-SY5Y human neuroblastoma cells. The aggregation of Aβ was markedly inhibited following treatment with silibinin in TH/β binding assay and TEM imaging assay. The presence of silibinin with Aβ increased cell viability, whereas its absence decreased it. Additionally, the level of H2O2 in Aβ-treated cells decreased following incubation with silibinin [50].

In animal experiments, silibinin ameliorates Aβ-induced short-term memory impairment as measured by a spontaneous alternation behavior task (Y-maze test) although no significant differences in the number of spontaneous locomotor activities were observed. Recognition memory in novel object recognition tests was improved by silibinin in Aβ-injected mice, while the amounts of time spent exploring objects in training and retention sessions did not differ. To further explore the effects of silibinin on Aβ-induced oxidative stress, levels of MDA and GSH were analyzed. Treatment with silibinin appeared to decrease MDA levels and increase GSH levels in the hippocampus [51]. The cued freezing response and contextual freezing response were attenuated in silibinin-treated animals, indicating an impairment in associative memory. However, silibinin did not change the level of response to electric foot shock (flinching, vocalization, and jumping) in either group. A significant increase in nitrotyrosine, TNF-α, and i-Nos levels in the hippocampus and amygdala were reduced following treatment with silibinin compared with distilled water [52] (Table 5).

### Discussion

The aggregation and accumulation of extracellular and intracellular Aβ induce impaired synaptic plasticity and memory [4]. Three proteases, such as α-, β-, and γ-secretases, cleave APP and generate the physiological peptide Aβ along with increased production of CTFs [53–55]. These soluble peptides spontaneously aggregate to form Aβ oligomers and fibrils that are subsequently deposited within the brain to form amyloid plaques [56]. The intracerebroventricular administration of Aβ peptide induces histological and biochemical changes, memory deficits, oxidative

damage, and inflammatory responses [4, 5]. Based on our review, berberine, GRg1, and silibinin appear to block the formation of Aβ via an inhibition of β-secretase activity. In addition, GRg1 suppressed γ-secretase activity.

The PI3K/Akt/GSK3β signaling pathway is associated with various aspects of AD pathology. PI3K regulates the trafficking of intracellular APP-CTFs, whereas GSK modulates APP processing and thereby influences the production of Aβ in neurons. Inhibition of PI3K contributes to tau phosphorylation and impairment in spatial memory. Suppressing GSK3 activity, which is induced by phosphorylation at specific serine residues (Ser 9 and Ser21) by Akt, has been demonstrated to contribute to the accumulation of Aβ in APP mice and the hyperphosphorylation of tau protein [57–62]. Berberine, curcumin, and puercarin regulated the PI3K/Akt/GSK3β signaling pathway. Berberine increased the phosphorylation of Akt and GSK3β, resulting in decreases of APP-CTFs levels. In vitro and in vivo data demonstrated that curcumin exhibits significant increases in the phosphorylation of Akt and GSK3β. Puerarin also upregulated the phosphorylation of GSK3β and Akt. The activation of glial cells and the expression of inflammatory mediators in conjunction with the presence of neurotoxic free radicals lead to neuroinflammation. Activated microglial cells induced by Aβ are able to engulf filament Aβ; thus, the decrease in the Iba-1 burden correlates with a reduced plaque burden [63–65]. Release of proinflammatory cytokines, such as IL-6, IL-1β, and TNF-α, along with chemokines is responsible for the initiation and progression of inflammatory responses [66–68]. Several studies have shown that IL-6 induces the processing of APP and regulates Aβ production [69]. Microglia and macrophages are a major source of TNF-α although TNF-α is also expressed to a lesser extent by GFAP-positive astrocytes, and IL-1β is expressed by neurons and astrocytes in response to AD-like pathology [66, 67]. High level of MCP-1 promotes the migration and recruitment of inflammatory cells [70, 71]. Furthermore, Aβ-induced MCP-1 mRNA expression is associated with the activation of the PI3K/Akt signaling pathway [72]. Additionally, NF-κB, and its key inhibitor, IκB-α, primary regulator of inflammatory processes in almost all cell types including neurons, are expressed in microglial cells that express i-Nos and Cox-2 [73, 74]. Previous studies have shown that the MAPK signaling pathways play an important role in the regulation of chemokine and pro-inflammatory cytokine production in microglia [75, 76]. Berberine, curcumin, and puercarin suppressed the activation of microglial cells and neuroinflammation by blocking the production of proinflammatory cytokines. Berberine, GRg1, and puercarin inhibited NF-κB and MAPK signaling pathways. In particular, berberine decreased the Iba-1 burden, indicating a reduction in the degree of microgliosis. In addition, treatment with berberine reduced IL-6 production and MCP-1 release in microglial cells. and suppressed NF-κB translocation into the nucleus as well as the phosphorylation of IκB-α, ERK1/2, and p38. Curcumin treatment showed a significant decrease in activated microglia along with reductions in IL-1β and TNF-α. In case of GRg1, the content of IL-1β, IL-8, and TNF-α were reduced with the phosphorylation of p38. And puercarin attenuated the phosphorylation of JNK and p38, resulting in the protection against neuronal cell death. Concerning neuron cell survival, the loss of neuron-related apoptosis is regulated by several intracellular signaling events [77]. During early apoptosis stages, the Bcl-2 protein family which includes anti-apoptotic molecules such as Bcl-2 and Bcl-xl, and pro-apoptotic molecules such as Bax, Bak, Bid, and Bad, is related to the formation of channels in mitochondrial membranes. The Bcl-2/Bax ratio, in particular, is crucial for initiating apoptosis, and its translocation to the mitochondrial membrane may lead to the loss of mitochondrial membrane potential and increased mitochondrial permeability [78] which results in the release of Cyt c from mitochondria and the subsequent activation of procaspase-3 to caspase-3, eventually leading to apoptosis [79]. GRg1 and

### Table 5

Summary of findings on silibinin as alternative treatment for Alzheimer’s disease.

puerarin attenuated apoptosis by regulating anti-apoptotic and pro-apoptotic molecules. GRG1 regulated the ratio of Bcl-2/Bax, resulting in the release of Cyt c from mitochondria and the reduction of caspase-9 and caspase-3 activities. Puerarin protected cell death via up-regulating the ratio of Bcl-2/Bax and down-regulating the caspase-9 and –3 activities which were induced by the phosphorylation of Bad.

Furthermore, it is well established that oxidative stress is involved in apoptosis in that excessive production of ROS can lead to neuronal apoptosis in AD [11,80]. GSH and MDA are important intracellular anti-oxidants necessary for the formation of peroxynitrite and responsible for removing oxygen-free radicals [51, 81]. In addition, the activations of NF-κB, Sirt1, and Nrf2 pathways are related to protection of cells against oxidant damage as stress sensor molecules [82]. Curcumin, GRG1, puerarin, and silibinin exhibited protection against oxidative stress. Specifically, curcumin regulated g-GCS expression and RNS level. And treatment with GRG1 inhibited the excessive generation of NO and MDA levels as well as ROS generation. Puerarin also decreased intracellular ROS generation while increasing GSH intracellular anti-oxidants necessary for the formation of peroxynitrite [82]. Curcumin, GRG1, puerarin, and silibinin decreased the levels of MDA, whereas GSH was increased in vivo study. Apart from the pathology, memory enhancement is one of major issues of AD. Loss of neurotranslators and markers, characteristic of striatal medium spiny neurons, belong to the process of neuronal cell death [83]. In terms of neurotoxic factors, BNDF promotes the survival of new hippocampal neurons [84]. Synaptic proteins take part in the development of nerve synapses and adjust their plasticity. SYN, one of the synaptic proteins, is a marker of synaptic distribution and synaptic density [85]. GRG1 increased SYN expression, and curcumin contributed to the formation of new neurons by regulating the synaptic proteins SYN and BNDF.

To date, evidence from recent studies suggests that commonly used medicinal herbs and their phytochemicals could potentially be used to treat AD. Although these studies focus on the efficacy of inhibiting AD development, and research on humans is limited, numerous findings demonstrate the possibilities of the use of medicinal herbs for the treatment of AD. The approach to investigate the potential treatment of AD may support drug development from herbal medicine.
