Hidden duodenal gastrointestinal stromal tumor

A 62-year-old woman was evaluated for iron deficiency anemia. She had no history of any medications, trauma, smoking, or alcohol consumption. On physical examination, the patient had a pale appearance, and tenderness in the epigastric region but no rigidity or rebound. Upper gastrointestinal endoscopy revealed the majority of the stomach and duodenal bulb to be normal. However, a well-hidden, red-colored, ulcerated lesion (diameter 2 cm) was observed. The lesion was located mainly on the posterior side of the duodenal bulb, partly occupying the duodenal bulb, and extended to the descending duodenum. The appearance and size of the lesion suggested a gastrointestinal stromal tumor (GIST), and it was therefore removed surgically. Histopathological examination of the resected tissue confirmed GIST. The patient was discharged 3 days after the surgery, and was doing well at follow-up.

GISTs are the most common submucosal tumors of the gastrointestinal tract, representing 1% – 3% of gastrointestinal malignancies. About 50% – 60% of GISTs occur in the stomach, and about 20% – 30% are malignant [1]. The duodenum is an uncommon location. Diagnosis of duodenal GIST is sometimes difficult, especially those arising in the posterior duodenal bulb. As peristalsis allows a better view of the duodenal bulb mucosa, observation of this area for a while during endoscopic examination is a feasible method of detecting hidden lesions.
