Asymmetric Total Syntheses of Aspidodasycarpine, Lonicerine, and the Proposed Structure of Lanciferine

*Y. Li, S. Zhu, J. Li, A. Li* (Shanghai Institute of Organic Chemistry and Shaoxing University, P. R. of China)

**Total Synthesis of Indole Alkaloids**

**Significance:** Indole alkaloids represent challenging synthetic targets due to their highly congested architecture and rich chemical functionality. Li and co-workers report the first enantioselective total synthesis of (−)-aspidodasycarpine and (−)-lonicerine. Furthermore, the synthetically obtained lanciferine did not match the previously reported spectroscopic data from the isolation literature.

**Comment:** Chiral amine C was obtained by a highly enantioselective transfer hydrogenation of imine A. The key C–C bond forming Conia-ene reaction of silyl enol ether D proceeded under gold catalysis to give tetracycle E. From precursor H, both (−)-aspidodasycarpine and (−)-lonicerine were obtained in four steps. The proposed structure of lanciferine was obtained from H in eight steps and was secured by X-ray crystallography.
