Copper-Catalyzed Enantioselective [1,3]-Rearrangement to Chiral Propargylic Amines

Significance: Thermal [3,3]-sigmatropic rearrangements are well precedentted and can be achieved at ambient temperature with high levels of enantioselectivity (see, for example: M. P. Watson, L. E. Overman, R. G. Bergman J. Am. Chem. Soc. 2007, 129, 5031). In contrast, [1,3]-sigmatropic rearrangements are thermally disallowed, but can be promoted at high temperatures with the use of transition-metal catalysts. No examples of [1,3]-rearrangements affording propargylic products or their enantioselective variants have been previously reported.

Comment: The present report details the first example of an enantioselective [1,3]-rearrangement. The alkyne starting materials 1 can be converted into pyridone alkydes 3 with a diverse substrate scope, affording products in high yields with high enantioselectivity. Detailed mechanistic studies indicate that the reaction proceeds through an allenyl intermediate 2 with copper coordination, followed by a formal [1,3]-rearrangement. The enantioselectivity is derived from a BINAP phosphoryl ligand through CuTC coordination. The synthetic utility of the products was shown by carrying 4 forward to the synthesis of cysteine protease inhibitor 11. This reaction will find utility due to the mild reaction conditions and the ability to modify the pyridine core to generate chiral amines similar to 10.
