Pyelonephritis in Pregnancy: Clinical and Laboratorial Aspects and Perinatal Results

Pielonefrite na gestação: aspectos clínicos e laboratoriais e resultados perinatais

Abstract

Objective To identify the prevalence of pyelonephritis during pregnancy and to analyze the clinical and laboratorial aspects, perinatal results and complications.

Methods A transversal study of 203 pregnant women who had pyelonephritis during pregnancy and whose labor took place between 2010 and 2016 at a hospital in the state of Santa Catarina, Brazil. The analysis was based on medical records as well as on the hospital’s database. Clinical and laboratory conditions, antibiotics, bacterial resistance, perinatal outcomes and complications were all taken into account. The data was compared using the Mann-Whitney test and the Chi-square test.

Results A prevalence of 1.97% with pyelonephritis was evidenced, with most patients having it during the second trimester of gestation. The bacteria most commonly found in the urine cultures was *Escherichia coli*, in 76.6% of cases, followed by *Klebsiella pneumoniae* (8.7%). Ceftriaxone had the lowest bacterial resistance (only 3.5% of the cases). On the other hand, ampicillin and cephalothin presented higher bacterial resistance, 52% and 36.2%, respectively. The risk of very premature delivery was more than 50% higher in patients with pyelonephritis.

Conclusion Ampicillin and first-generation cephalosporins are associated with a higher bacterial resistance while ceftriaxone proved to have a high efficacy for the treatment of pyelonephritis due to low bacterial resistance. Patients with pyelonephritis showed a higher risk for very premature delivery (< 32 weeks). In this casuistry, there were no others significant differences in the overall perinatal outcomes when compared with the routine service series.
Introduction

Urinary tract infections (UTIs) have great relevance in the gestational period, specially pyelonephritis, which is one of the most common causes of hospitalization during the prenatal period.\(^1\) Despite the decrease in the incidences of pyelonephritis in recent years due to improved follow-up during prenatal care, the development of a resistance to antibiotics and other factors may influence its diagnosis and treatment.\(^2\)

Asymptomatic bacteriuria (ASB), defined by a urine culture collection that presents > 100,000 colony forming units (CFU) of a single pathogen, substantially increases the risk of pyelonephritis during pregnancy. The treatment of ASB reduces the chance of pyelonephritis from 20–35% to 1–4%, and it also prevents low birth weight and intrauterine growth restriction.\(^3,4\)

There is a predisposition to pyelonephritis in the gestational period and it is mainly due to physiological changes that occur during gestation. From the 12th week of gestation, it is possible to observe ureteral dilatation as well as renal calices due to the progesterone-induced relaxation. Therefore, there is a decrease in ureteral peristalsis, which together with ureteral enlargement and ureteral compression, especially on the right side, as well as compression of the bladder, with consequent loss of emptying capacity, associated with increased urine output, may contribute to urine stasis.\(^5,6\)

The clinical findings of pyelonephritis are: fever with abrupt onset, acute pain that may be exacerbated by the maneuver of the cuff-percussion at costovertebral angles, nausea and vomiting.\(^7\) Identification of the pathogen for diagnosis and treatment planning is done by urine culture.

The most common uropathogen in urine samples is *Escherichia coli*, present in ~ 95% of the cases of pyelonephritis in pregnant women.\(^8\) Other microorganisms can also be found on a smaller scale such as: *Klebsiella pneumoniae*, *Enterobacter aerogenes*, *Proteus mirabilis*, *Enterococcus faecalis* and group B *Streptococcus*.\(^9\)

Most pregnant women diagnosed with pyelonephritis should be initially hospitalized for empirical treatment until the result of the uroculture for pathogen identification and the antibiotic sensitivity test (AST). According to Artero et al.\(^10\) Amoxicillin-Clavulanate and Cephalosporin have shown to be adequate choices for empirical treatment. In untreated cases of pyelonephritis, there is an increased risk of fetal and maternal morbidity such as fever, renal failure, preterm birth and stillbirth.\(^11\) Additionally, sepsis can be one of the most feared complications among pregnant patients, increasing the risk of acute respiratory distress syndrome and a higher risk of emergent cesarean delivery.\(^12\)

Taking into account these considerations, this study aims to evaluate clinical and laboratory findings, as well as perinatal complications associated with pregnant women diagnosed with pyelonephritis, to contribute to the understanding of the risks associated with the disease and to provide clarification for public health purposes.

Methods

An observational and cross-sectional study was conducted at a maternity of a public university hospital in Florianópolis, Brazil.

The collection was performed via an electronic database containing information on the medical records of all pregnant women attended between January of 2010 and December of 2016 who had the diagnosis of pyelonephritis. During this period, there were 10,291 births of single fetuses and 203 pregnant women diagnosed with pyelonephritis. All cases of twinning, abortion (birth weight less than 500 g or gestational age [GA] ≤ 20–22 weeks) and 11 cases in which hospitalization due to pyelonephritis occurred at another hospital were excluded.

The diagnose of pyelonephritis was defined by the presence of a positive urine culture (> 100,000 CFU of organisms)
as well as at least one of the clinical findings: fever (> 37.8°C), costovertebral angle pain and flank pain.

Demographic and clinical data from patients who had the diagnosis of pyelonephritis during the gestational period were obtained through hospital electronic records followed by charts review. The search was guided by a pre-established study protocol. The following variables and outcomes were evaluated: leukocyturia (> 10,000 white blood cells/ml), anemia (hemoglobin < 11), need for intensive care unit (ICU), diabetes, systemic arterial hypertension (blood pressure over 130/85 mmHg), human immunodeficiency virus (HIV), use of illicit drugs, length of hospital stay, days of treatment, antibiotic in use and antibiogram.

Data from 6,010 births within the same period were used for comparison of perinatal outcomes in women with no history of pyelonephritis or diseases prior to pregnancy (58.4% of all single births). The following variables were analyzed: APGAR score, weight at birth, postpartum hemorrhage, preeclampsia and cesarean section and GA at birth, which was divided in premature delivery (GA < 32 weeks) and very premature delivery (GA < 28 weeks) and very premature delivery (GA < 37 weeks) and very premature delivery (GA < 32 weeks) and very premature delivery (GA < 37 weeks) and very premature delivery (GA < 32 weeks).

All the variables in the research were analyzed through the software SPSS 16.0 (SPSS Inc., Chicago, IL, USA), the quantitative variables were compared through the Mann-Whitney test and the qualitative variables through the Chi-square. Values of \( p < 0.05 \) were considered statistically significant.

The research was approved by the Human Research Ethics Committee (HREC) in Brazil, under the protocol number 461.143.

During this research, there were no conflicts of interest identified by the authors.

**Results**

Total 10,291 single-fetal births were recorded between January of 2010 and December of 2016. Two-hundred and three of the pregnant patients were diagnosed with pyelonephritis at some time during pregnancy, resulting in a prevalence of 1.97%.

Most of the pregnant women diagnosed with pyelonephritis were in the second trimester of gestation (54.6%). Only 10.9% of the pregnant women were in the first trimester of pregnancy at the time of diagnosis. The mean GA was 24.1 weeks with a standard deviation (SD) of 4.7 at the time the infection was diagnosed.

The most common clinical and laboratory findings were: leukocyturia (94.7%), fever (80.2%) and pain in the costovertebral angle (72.3%). Anemia was evident in 21.8% of the patients (Table 1).

Regarding prenatal care, it was observed that of the 192 pregnant women hospitalized for pyelonephritis, 161 (83.9%) were already under regular follow-up.

Most patients remained hospitalized for less than 7 days (91%) and required less than 7 days of intravenous antibiotic therapy (92.1%). More than half of the patients in intravenous treatment (46.3%) did not require hospitalization for longer than 3 days. Patients who had extended hospital stay, for a period longer than 7 days, were the most severe cases, in which the majority required intensive care unit (ICU) hospitalization.

Among the 192 cases analyzed, it was not possible to identify the bacteria in the urine culture of 21 of them (10.9%). It is verified that the bacteria of highest incidence in the urine culture corresponds to *Escherichia coli*, isolated in 76.6% of the antibiograms in which the agents were identified, followed by *Klebsiella pneumoniae* (8.7%) and *Proteus mirabilis* (4%), as demonstrated in Table 2.

The most commonly used antibiotic for the intravenous phase was ceftriaxone, used in 197 patients (97.4%). In three cases, it was associated with gentamicin. Cephalothin was prescribed in three cases and amicacin or cefoxitin with gentamicin was used in only one patient for each regimen.

According to Table 3, among the antibiotics tested, the highest bacterial resistance index involve ampicillin (52%) and first-generation cephalosporin (36.2%). Ceftriaxone had

the lowest bacterial resistance index, evidenced in only 6 patients. A result similar to the one of the quinolone studied, which obtained only 3.5% of resistance in total and to that of ceftazidime (4%) (∗Table 3).

The mean birth weight of the children of patients with pyelonephritis was 3,211.3 g with a standard deviation (SD) of 282.3, similar to the average birth weight of 3,218.3 g (SD 432.1) (p = 0.781). For pregnant women who had pyelonephritis, the mean GA for delivery was 39.1 weeks (SD 1.2), while the mean GA for the other women was 38.9 weeks (SD 1.6) (p = 0.617).

According to the perinatal results shown in ∗Table 4, patients diagnosed with pyelonephritis had a greater risk of very premature delivery (3.3%) compared with only 1.2% of patients with no prior history of the infection (p < 0.023).

Discussion

There is a consensus in scientific studies that pyelonephritis in pregnancy causes an increase in maternal and fetal morbidity, as well as an increase in the hospitalization of pregnant women. Among the complications related to pyelonephritis, anemia, septicemia with consequent need for ICU, fever and fetal changes, such as low birth weight and premature delivery, are prominent.10,13

In this study, the collection performed through the available database presents some limitations, since the information regarding the clinical history of the patients studied were written by different professionals.

A prevalence of 1.97% of pregnant women with pyelonephritis was found during this study, a result that is in agreement with other studies such as the one by Hill et al.,9 in which a value of 1.4% was found.

Most of the diagnosed pregnant women were in the second and third trimester of gestation (88.9%), which is in agreement with findings by Dawkins et al.2 It is believed that this finding correlates with the peak period of urinary stasis and immunological changes in the urinary tract due to hormonal influence.9

Regarding laboratory findings, anemia is one of the most common complications of pyelonephritis, present in ~25% of patients, a finding similar to the one in the present study (21.8%).9 Despite the difficulty of identifying the type of anemia, it is known that hemolytic anemia is more common in pregnant women with pyelonephritis due to the activity of bacterial endotoxins and consequent erythrocyte destruction.14

Dawkins et al.2 in a study conducted in Jamaica, showed that 81.4% of the women had leukocyturia, which was also the most frequent alteration in the present study. Although the basic urine test can translate a possible UTI, this test will actually show signs of inflammation in the urinary tract, not necessarily an infection.15 Due to its low specificity, other conditions like pelvic inflammatory disease, gomerulonephritis and sexually transmitted diseases can also have a positive white blood cell count in the urine.16

A group of 17 patients (8.8%) who were diagnosed with pyelonephritis required a longer than usual hospital stay, and 7.2% of them needed ICU care. They were patients who had some...
type of complication and, consequently, were in need of care in the ICU and/or surgical procedure. More serious complications may occur due to endothelial damage in capillaries, caused by an immune response to endotoxins from gram negative bacteria, resulting in an increased risk of septic shock, respiratory failure, and disseminated intravascular coagulation.5

All the authors indicate Escherichia coli (E. Coli) as the main microorganism involved in the diagnosis of pyelonephritis, which coincides with the results found in (76.6%) the urine cultures analyzed at the hospital.2,9,10,17,18 After E. coli, the most common microorganisms were Klebsiella pneumoniae (8.7%) and Proteus mirabilis (4.0%). There was no pathogen identification in ~11% of the patients, possibly due to previous antibiotic therapy or method limitations.

The antibiotic used as the first choice was ceftriaxone, which showed low bacterial resistance (3.5%). First-generation ampicillin and cephalosporin (cephalothin) were the antibiotics that showed the highest bacterial resistance, 52% and 36.2% of the cases, respectively. Thus, we recommend avoiding the use of these routine antibiotics. In contrast, Artero et al10 used amoxicillin with clavulanate and cephalosporins as the first choice, finding a resistance of 14% with amoxicillin and clavulanate in E. coli infections. Studies have found similar results regarding bacterial resistance to ampicillin (49%) and a higher rate of antibiotic therapy replacement.10,19 According to the International Guideline of the Society of Infectious Diseases of America and the European Society of Microbiology and Infectious Diseases, for the treatment of pyelonephritis, ampicillin, as well as amoxicillin, should not be routinely used for empirical treatment because of the great resistance to both antibiotics.20

In this study, there was no statistically significant difference in overall prematurity when compared with patients without the diagnosis of pyelonephritis during pregnancy. Nonetheless, a study conducted in the United States found different results, showing that patients with pyelonephritis are more likely to have preterm birth when compared with non-diagnosed patients (10.3% versus 7.9%, respectively).19 In the subgroup of very premature (<32 weeks), however, the history of pyelonephritis increased the chance of prematurity by more than 50%. The study by Wing et al21 also suggests that patients treated for pyelonephritis at the end of gestation have a higher incidence of preterm birth.

The incidence of low birth weight of 6.7% is relatively low when compared with other studies such as that of Sharma et al22 who found a value of 13.82%. This difference may be related to improved follow-up after the treatment of pyelonephritis, but also to the characteristics of the population studied.

Regarding patients with pyelonephritis, when analyzing the incidence rate of cesarean section, the number of patients with increased bleeding postpartum, and patients with preeclampsia, no significant differences were found when compared with the values of patients who did not have the diagnosis of the infection. A study in the USA conducted by Dotters-Katz et al13 showed clinical and statistical difference in which pregnant women with pyelonephritis had lower rates of cesarean section, postpartum hemorrhage and preeclampsia compared with patients without the prognosis (p < 0.0001).

**Conclusion**

In conclusion, the study showed an increased risk for very premature delivery (<32 weeks) in patients who had pyelonephritis during pregnancy. This research also indicates that the use of ceftriaxone for the treatment of pyelonephritis during pregnancy is an adequate choice due to low bacterial resistance. These findings may be useful for updating protocols and routines.
