Abstract Biologically attractive azaspiro[4.5]trienones have been prepared via Ugi four-component reaction (Ugi-4CR) followed by bromine-mediated *ipso*-cyclization. This allows a straightforward synthetic route to a diverse collection of fully functionalized 3-bromoazaspiro[4.5]trienones in moderate to good yields that can be used as templates for further modifications.

Key words alkynes, spiro compounds, cyclization, radical reaction, ring closure

Azaspirocycles, which are nitrogen-containing spirocyclic scaffolds, play significant roles in synthetic and medicinal chemistry. Literature searches on azaspirocyclic scaffolds have shown that these derivatives possess a broad spectrum of biological and pharmacological properties such as antimitotic, cytotoxic, antibacterial, antimicrobial, anti-inflammatory, antioxidative and antidepressant activities.¹ A few examples of natural and synthetic drugs containing an azaspirocyclic skeleton are shown in Figure 1.² Consequently, great efforts have been made to synthesize diverse azaspirocycles libraries to facilitate the incorporation of these moieties into more biologically and pharmaceutically active molecules.^{3–7}

Among the recently synthesized azaspirocycle-containing compounds, azaspiro[4.5]trienones have attracted a great deal of attention due to their chemistry and their biological activities.⁸ Very recently, and in the light of the intense interest to develop constrained tamoxifen mimics,

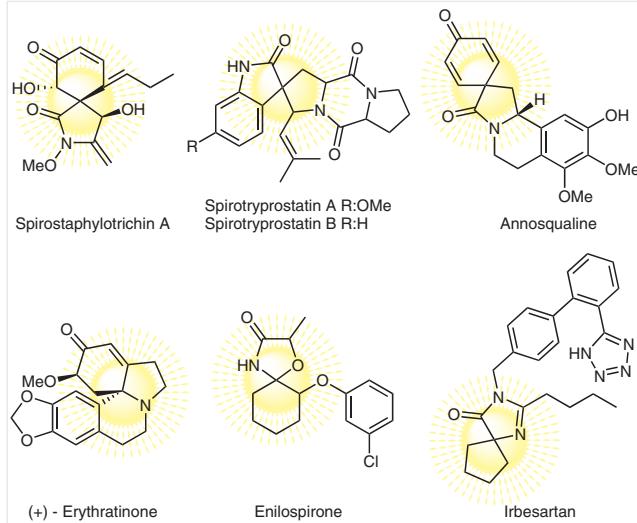

Figure 1 Structures of some natural and synthetic drugs containing an azaspirocyclic skeleton

Srivastava et al. reported azaspiro[4.5]trienones as novel scaffolds for anticancer drug development (Figure 2, top structure).⁹ Furthermore, these compounds serve as valuable intermediates for the construction of azaspiro-fused tricyclic cores with promising anticancer activity by inducing DNA damage (Figure 2).^{10–12} Therefore, more attention has been drawn to the synthesis of functionalized azaspiro[4.5]trienones suitable for further derivatization processes.^{13–15}

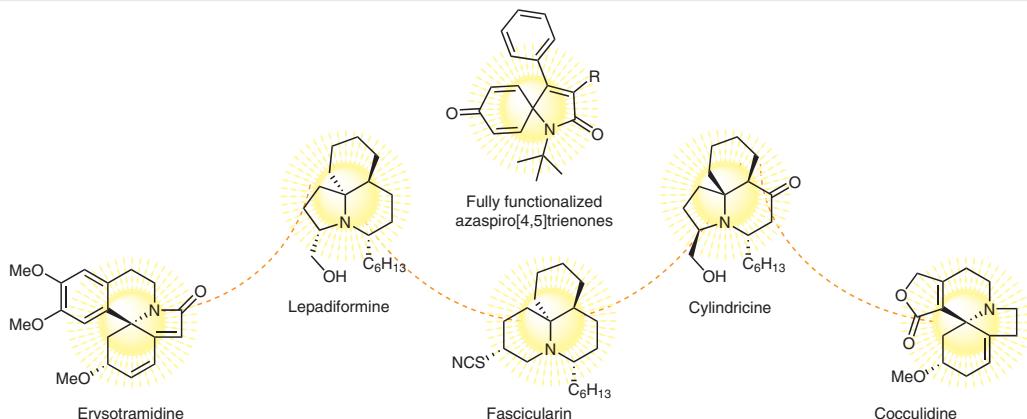

Figure 2 Recently reported cytotoxic azaspiro[4.5]trienones and cytotoxic alkaloids with azaspiro-fused tricyclic cores

Brominated substrates are excellent synthons for further functionalization because they can be further used in well-established cross-coupling reactions, whereas other approaches to such transformations are complex and often result in significant by-product formation.¹⁶ In this respect, especially in light of the fact that brominated triene-diones are ideal scaffolds for further elaboration in the diversity-oriented synthesis, Qiu et al. have recently described the synthesis of 3-bromo-1-azaspiro[4.5]deca-3,6,9-triene-2,8-dione through a novel ZnBr₂-promoted oxidative *ipso*-annulation of *N*-arylpropiolamide.⁵

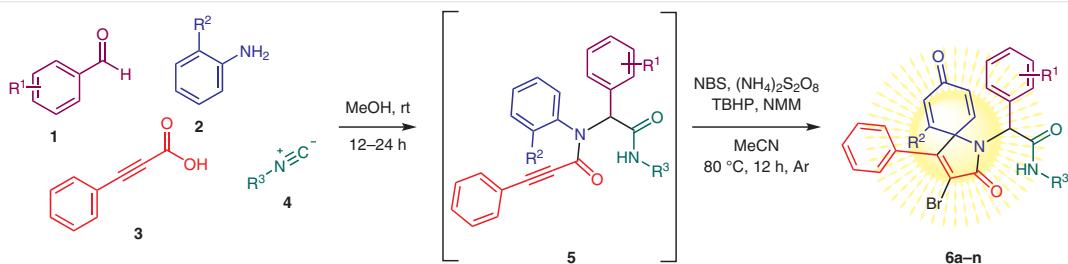

In light of these findings and as a result of our interest in combination of the Ugi four-component reaction (Ugi-4CR) with efficient post-transformations for generating complex and diverse molecular libraries,¹⁷ we wish to report herein, a simple procedure for the synthesis of fully functionalized 3-bromoazaspiro[4.5]trienones via Ugi-4CR followed by *ipso*-bromocyclization (Scheme 1).

Ugi 4-CR of 4-methoxybenzaldehyde (**1a**), aniline (**2a**), phenylpropionic acid (**3**), and *tert*-butyl isocyanide (**4a**) in methanol at room temperature furnished the corresponding Ugi adduct **5a** in 83% yield. This compound was chosen as the model substrate to investigate the bromine-mediated *ipso*-cyclization conditions. Application of (NH₄)₂S₂O₈/TBHP (3 equiv/5 equiv) as the oxidant in the presence of *N*-methylmorpholine (NMM, 0.5 equiv) in acetonitrile at 80 °C un-

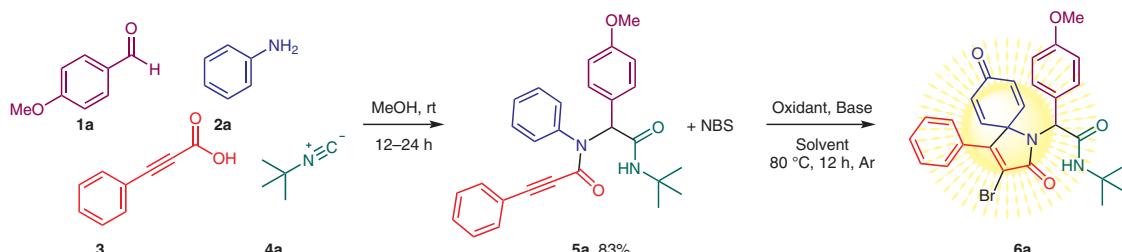

der argon atmosphere produced the desired product **6a** with a yield of 88%. After screening solvents under these conditions, acetonitrile was found to be the best solvent (Table 1, entries 1–7). When *N*-methyl-2-pyrrolidone (NMP) was used in place of NMM, a marginal decrease in yield was recorded (entry 8). The application of NMM gave **6a** with a yield of 88%, while replacement with triethylamine (TEA), 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) and *N,N*-diisopropylethylamine (DIEA) resulted in lower yields (entries 9–11). Other radical initiators including di-*tert*-butyl peroxide (DTBP), benzoyl peroxide (BP), and *m*-chloroperoxybenzoic acid (*m*-CPBA) were then employed, but all failed to give satisfactory yields (entries 12–14).

After carrying out the Ugi 4-CR, the solvent was evaporated under reduced pressure, and the conditions were switched for the bromine-mediated *ipso*-cyclization, which gave compound **6a** in 67% overall yield, comparable with the 73% total yield obtained in the two-step procedure. Subsequently, the scope of the reaction was investigated by using different aromatic aldehydes, anilines, and isocyanides (Scheme 2).¹⁸

The structures of the products were confirmed based on NMR spectroscopy and HRMS (ESI) analysis. The characteristic resonances in the ¹H NMR spectra of all synthesized compounds appeared as four double doublets with coupling constants 9.9 and 1.8 Hz for the sp² C–H. The ¹³C NMR spec-

^a Optimal reaction condition: **5a** (1 equiv), NBS (1.5 equiv), (NH₄)₂S₂O₈ (3 equiv), TBHP (5 equiv), and NMM (0.5 equiv) in MeCN (2 mL) at 80 °C under argon atmosphere for 12 h.

^b Isolated yield.

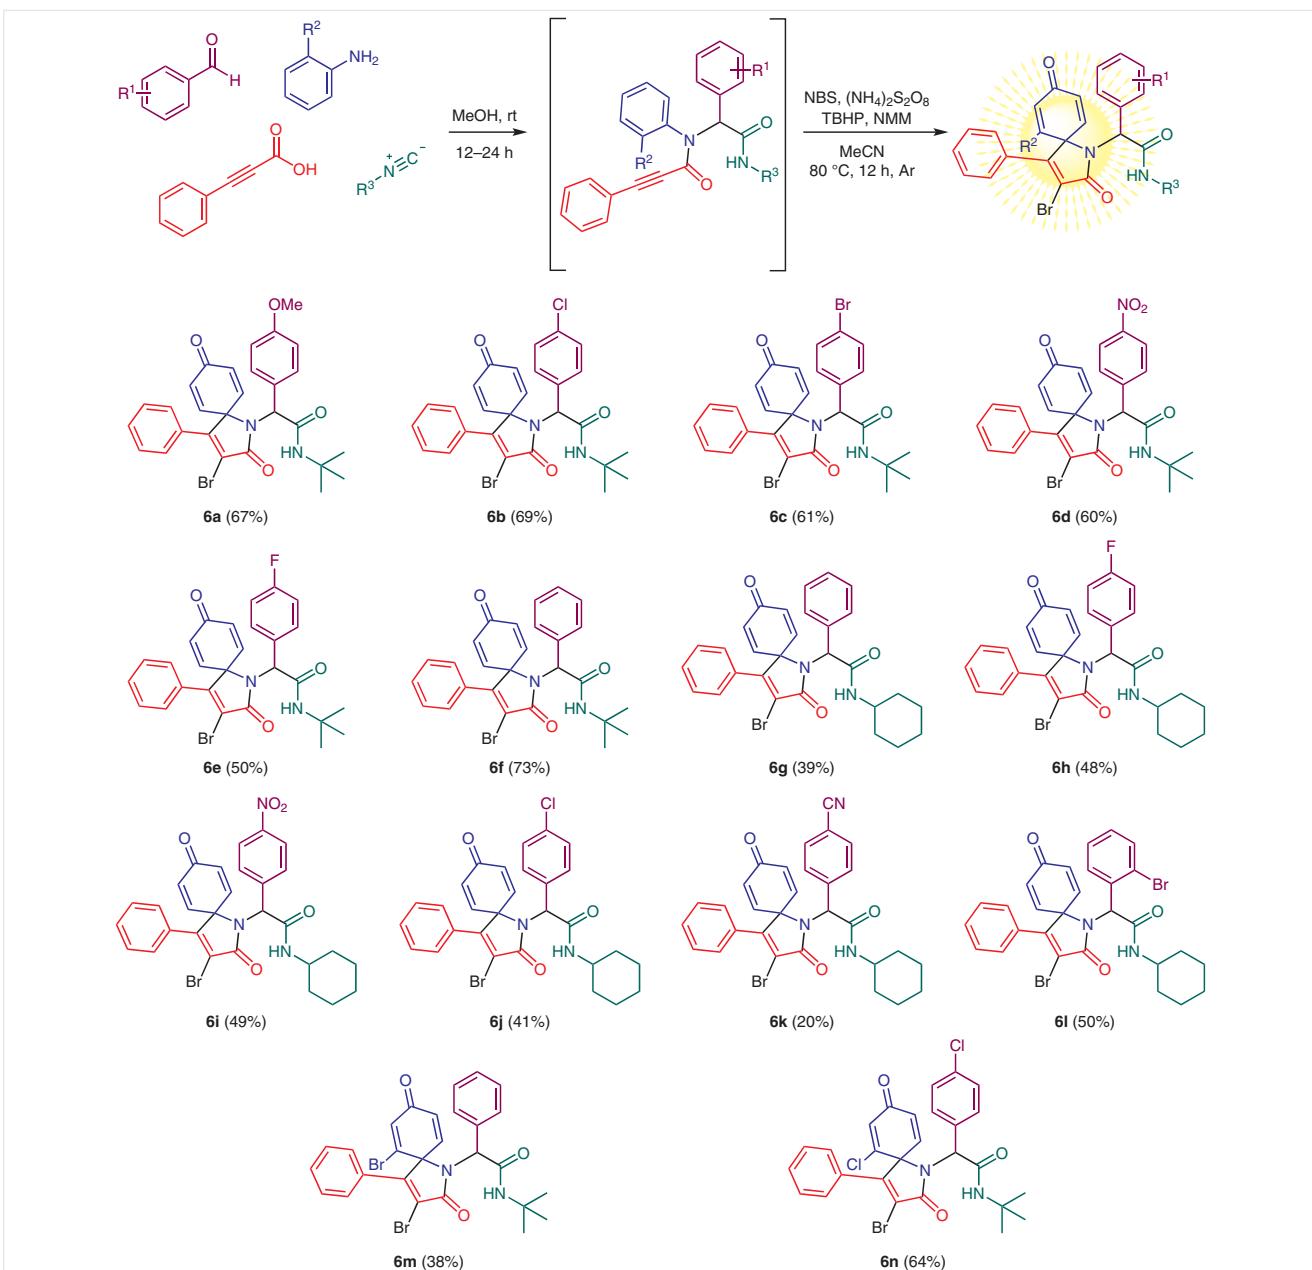

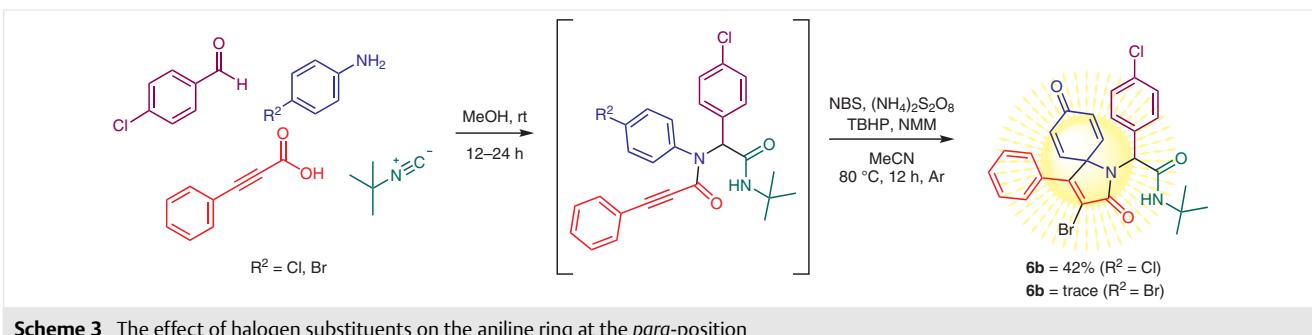

^c This reaction was performed at room temperature.

tra of compounds exhibited characteristic signals at δ = 165.6, 166.9, 184.0 ppm associated with the carbonyls of the amidic moieties and unsaturated ketone.

Initially, the effect of ring substituents on the aromatic aldehydes **6a–f** was examined. Both electron-donating and electron-withdrawing substituents on the phenyl ring were tolerated as outlined (Scheme 2). With regard to the isocyanide component, *tert*-butyl isocyanide furnished the desired products in better yields than cyclohexyl isocyanide. A survey of aniline derivatives with differing substitution pat-

terns revealed that aniline derivatives bearing substituents at the *ortho*-position were consistent with the optimal conditions, providing **6m** and **6n** in moderate to good yields.

Treatment of *para*-halogen-substituted anilines with 4-chlorobenzaldehyde (**1b**), phenylpropionic acid (**3**), and *tert*-butyl isocyanide (**4a**) delivered product **6b**, but the reaction did not proceed at all when the aniline ring contained a *para*-nitro group (Scheme 3). It is noteworthy that, in all cases where yields were lower than average, the reaction was inefficient at the *ipso*-bromocyclization step, with a complex mixture of products being obtained.

**Scheme 2** Substrate scope for the synthesis of fully functionalized 3-bromoazaspiro[4.5]trienones **6a–n****Scheme 3** The effect of halogen substituents on the aniline ring at the *para*-position

Crude products were purified on a silica gel column ($\text{EtOAc}/n\text{-hexane}$, 1:5) and the purified compounds were fully characterized by IR, ^1H NMR, ^{13}C NMR spectroscopy and HRMS analysis. In addition, in the case **6a**, the structure was confirmed by single-crystal X-ray diffraction analysis (Figure 3).

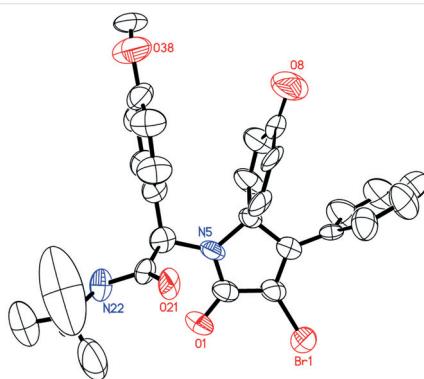

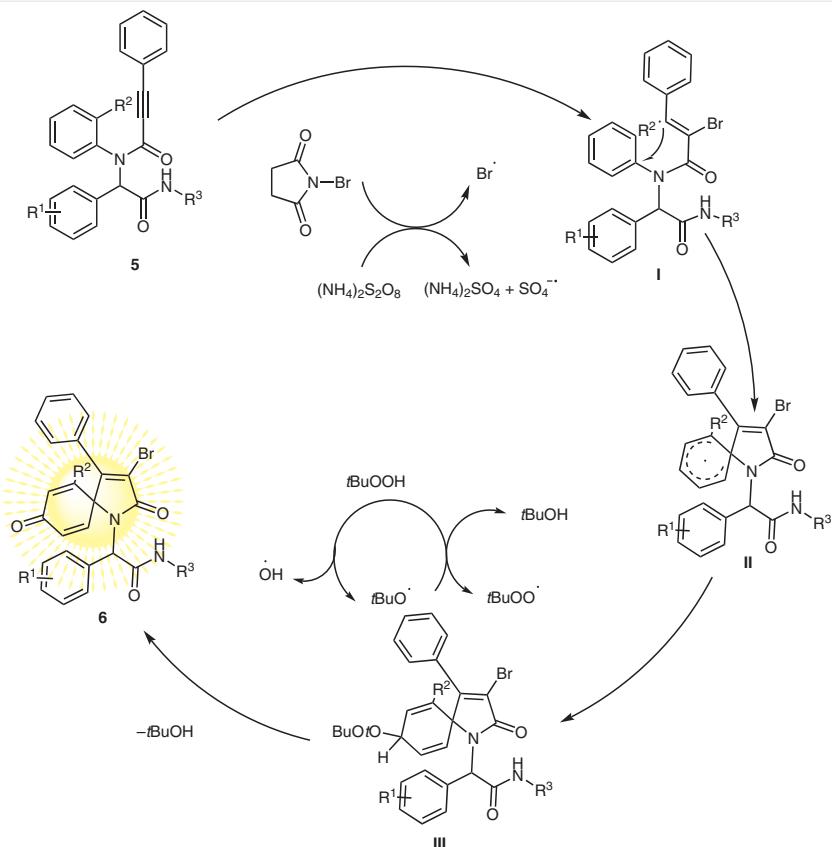

Figure 3 ORTEP view of compound **6a**

The proposed reaction mechanism involves the formation of vinyl radical **I** through the addition of a bromo radical generated from NBS and $(\text{NH}_4)_2\text{S}_2\text{O}_8$ to the alkyne group of the Ugi product. Subsequent intramolecular radical cyclization yields the intermediate **II**. Trapping of the radical intermediate **II** by the *tert*-butylperoxy radical generated from TBHP, and then elimination of *tert*-butyl alcohol provides the desired product (Scheme 4).

In conclusion, we have prepared a diverse array of fully functionalized 3-bromoazaspiro[4.5]trienones through Ugi-4CR followed by *ipso*-bromocyclization. Considering the biological importance of azaspiro[4.5]trienones and the potential utility of the bromo organic compounds to partake in further modifications, these compounds can be further exploited in the synthesis of lead compounds in medicinal chemistry.

- (18) **Sequential U4-CR/*ipso*-Bromocyclization to Synthesize Compounds 6a–o; General Procedure**
To a solution of aldehyde **1a** (1 mmol) in methanol (5 mL) was added aniline **2a** (1 mmol), and the reaction mixture was stirred at room temperature for 2 h. Then, phenylpropionic acid **3a** (1 mmol) was added and stirring was continued for 15 min, followed by addition of isocyanide **4a** (1 mmol); the solution was then stirred for 24 h at room temperature. The solvent was removed under reduced pressure and MeCN (10 mL) was added to the residue. *N*-Bromosuccinimide (1.5 mmol), (*NH*4)2S2O8 (3 mmol), TBHP (5 mmol) and NMM (0.5 mmol) were added and the reaction mixture was stirred at 80 °C for 12 h under an argon atmosphere. The progress of the reaction was monitored using TLC (*n*-hexane-EtOAc, 5:1). The resulting reaction mixture was concentrated under reduced pressure and the residue was purified by column chromatography (silica gel, appropriate mixture of *n*-hexane/ethyl acetate) to afford **6a**.
