Published as part of the 50 Years SYNTHESIS – Golden Anniversary Issue

Abstract
The first total synthesis of natural (+)-cycloclavine uses a catalytic asymmetric cyclopropanation of allene, a regiospecific Pd-catalyzed enone formation, and two intramolecular Diels–Alder reactions for indole/indoline annulations. The binding properties of natural (+)- and unnatural (–)-cycloclavine on 16 CNS receptors revealed significant stereospecificity and unique binding profiles in comparison to LSD, psilocin, and DMT. Differential 5-HT affinities, as well as novel sigma-1 receptor properties bode well for potential therapeutic developments of clavine alkaloid scaffolds.

Key words clavine ergot alkaloids, enantioselective allene cyclopropanation, psychedelics, stereospecific GPCR binding, LSD, psilocin, DMT, 5-HTA, sigma-1 receptors

While the unique properties of naturally occurring compounds have always fascinated researchers from all branches of Science, the total synthesis of alkaloids currently experiences a remarkable renaissance, motivated by the complex architectures, diverse functionalities, and profound biological and cultural impact of this large family of natural products. Indole alkaloids, in particular, are attracting significant attention in Chemistry and Medicine. With the goal to explore both innovative synthetic strategies and new biological applications, we have recently established a program in the total synthesis of ergot alkaloids of the clavine and lysergic acid subclasses (Figure 1).

In 1969, A. Hofmann and co-workers at Sandoz in Basel, Switzerland, reported the isolation of a novel, cyclopropane-containing ergot alkaloid, (+)-cycloclavine, from the seeds of the morning glory Ipomoea hildebrandtii VAT-KE, collected in Nairobi, Kenya. After a latency of almost 40 years, cycloclavine has now become a popular target for organic synthesis, and a number of groups have reported innovative synthetic approaches. In pioneering studies from the group of Szántay, 4-bromo-Uhle's ketone was subjected to an alkylation and intramolecular aldol reaction with 3-methylaminopropanoate, and the first synthesis of (±)-cycloclavine was completed in 2008 by a cyclopropanation of a tetrasubstituted alkene with CH2N2 (Scheme 1).

Motivated by our interests in the synthetic and medicinal chemistry of indoles, the structurally unique indoline-indole scaffold of cycloclavine served as our first ergot alkaloid target. In 2011, we developed an intramolecular SN2-displacement and furan Diels–Alder reaction for the formation of the fused pentacyclic ring system and the synthesis of (±)-5-epi-cycloclavine. Subsequently, we modified this approach and used an intramolecular Diels–Alder reaction to a strain-activated methylenecyclopropane for the construction of the indoline segment and the total synthesis of (±)-cycloclavine (Scheme 1).

In 2014, Brewer and co-workers used a fragmentation and an azomethine ylide 1,3-dipolar cycloaddition to construct racemic cycloclavine (Scheme 2). Cao’s group deve...
oped two formal syntheses of racemic cycloclavine and a formal synthesis of (+)-cycloclavine starting from substituted indoles and intersecting with the late stage alkene in Szántay’s synthesis.9

Another formal synthesis of (±)-cycloclavine that converged with Szántay’s approach was accomplished by Netz and Opatz in 2016, utilizing a β-alkylation of a pyrrolinone followed by a Heck coupling.10

The first asymmetric synthesis of (–)-cycloclavine, the enantiomer of the natural alkaloid, was accomplished by our group in 2017.11 Key features of this synthesis were a catalytic asymmetric cyclopropanation of allene, an intramolecular Diels–Alder reaction to methylenecyclopropane (IMDAC), and an intramolecular Diels–Alder reaction to furan (IMDAF). Subsequently, a formal synthesis of both enantiomers of cycloclavine was realized by Bisai and co-workers based on a D- or L-proline catalyzed α-aminokation and a Heck coupling (Scheme 2).12 Most recently, Dong and co-workers developed a benzyne cycloaddition/alkene carboacylation route to both (–)-5-epi-cycloclavine and (–)-cycloclavine, utilizing a ring-enlargement of a benzocyclobutenone intermediate as a key reaction.13 The impressive publication surge and the diverse strategies of these synthetic approaches illustrate the high level of current interest in architecturally novel alkaloid natural products. We now report the details of the first enantioselective total synthesis of (+)-cycloclavine.

Our retrosynthetic analysis is summarized in Scheme 3. In analogy to our route to (–)-cycloclavine,11 we selected an asymmetric rhodium-catalyzed cyclopropanation of allene with a diazopropanoate active ester, followed by an amino-lysis with 4-(methylamino)but-3-en-2-one, for the assembly of the key precursor for the IMDAMC reaction. After installing the enone in the six-membered ring by a Diao–Stahl ketone dehydrogenation,14 the thermally removable Tempoc group for amine protection15 would be used to stabilize an aminomethyl lithium reagent and favor enone 1,2-addition versus lactam ring opening. The final indole ring fusion was envisioned to be accomplished by the IMDAF cycloaddition.6b,d,l7,16
For the realization of this retrosynthetic plan, two building blocks and a chiral ligand needed to be prepared and optimized at the onset of the synthesis. The condensation of pyruvic acid (2) with tosyl hydrazide (1) under acidic conditions provided hydrazone 3 in 93% yield (Scheme 4). Treatment with oxalyl chloride and esterification of the resulting acid chloride with pentafluorophenol (PfOH) delivered an active ester intermediate suitable for rapid segment assembly. Base-mediated diazo formation produced the first building block 4 in 21% yield.

Next, we focused on the selection of an appropriate transition metal catalyst and chiral ligand for the asymmetric allene cyclopropanation step. Diazopropanoates 5 are challenging reagents for use in metal-mediated cyclopropanations because of the propensity of the metal carbeneoid to undergo competing β-hydride migration to form an acrylic ester 7 (Scheme 5). In the past decade, several methods have emerged that address this limitation. Fox et al. found that dirhodium complexes with sterically hindered carboxylate ligands in conjunction with low reaction temperatures effectively promoted intermolecular cyclopropanations over the competing β-H migration pathway.17

Among the enantioselective variants, bulky carboxylates derived from L-tert-leucine, such as Rh₂(S-PPTL)₄ (8), were found to be particularly effective. More recently,
Hashimoto et al. showed that the substrate scope could be further expanded when the dirhodium complex \( \text{Rh}_2(\text{S-TBPTTL})_4 \) (9) was used as the catalyst (Figure 2).\(^\text{18}\) We also prepared the enantiomer of 9, \( \text{Rh}_2(\text{R-TBPTTL})_4 \) (10), from \( \text{d-}\text{tert-leucine} \) [(R)-18] and anhydride 17 in toluene at reflux, followed by a ligand exchange reaction with \( \text{Rh}_2(\text{OAc})_4 \) in a chlorobenzene/MeCN mixture at 130 °C (Scheme 6). Furthermore, we reasoned that the 4,7-diphenyl substitution pattern on the phthalimide ring of the novel, sterically demanding dirhodium catalyst 11 would impose even greater steric discrimination than the corresponding bromide substituents in 9 and 10, hopefully leading to greater differentiation between the enantiotopic faces of the allene. This catalyst was prepared in a Diels–Alder reaction of diphenylbutadiene (19) and maleic anhydride (20), followed by DDQ oxidation to afford anhydride 21, which was reacted with (S)-18 in the presence of triethylamine to give 22 and subjected to a ligand exchange reaction to yield 11 (Scheme 7).

The results of the cyclopropanation of allene (23) with pentafluorophenyl diazopropanoate (4) to give methyleneacyclop propane 24 in the presence of the chiral catalysts 8–16 are summarized in Table 1. Rh(II)-Catalysts with sterically hindered amino acid ligands but lacking phthalimide substituents, such as 8 and 12, provided a low e.r. of approximately 7:3 (Table 1, entries 1 and 5). Hashimoto’s tetrabromomethylalyl tert-leucine dirhodium catalyst 9 resulted in a notable improvement, giving the cyclopropane (R)-24 in a high yield with an e.r. of 87:13 (entry 2). As expected, the (R)-tert-leucine derived 10 gave the enantio-meric product (S)-24 in identical yield and e.r. (entry 3). Disappointingly, however, virtually no enantioinduction was observed when allene was reacted with 4 in the presence of the sterically more demanding dirhodium catalyst 11 (product e.r. = 55:45, entry 4). With this catalyst, no reaction occurred at –78 °C and the mixture had to be warmed to –40 °C before conversion was observed. The chiral cyclopropane catalyst 13 delivered the desired product 24 in moderate yields and with poor enantioinduction (entry 6). Davies’ proline-based catalyst 14 also provided only a moderate yield of 61%, and negligible asymmetric induction (entry 7). The reaction of Ru(II)-catalyst 15 did not deliver any of the desired product. Instead, upon warming the reaction mixture from –78 °C to room temperature, full conversion into the undesired β-H migration product 25 was observed (entry 8). Similarly, the (salen)cobalt(II) catalyst 16 showed no catalytic activity even at room temperature (entry 9).

In our synthetic route, the cyclopropanation of allene (23) with diazopropanoate 4 in the presence of 1 mol% of the dirhodium catalyst \( \text{Rh}_2(\text{R-TBPTTL})_4 \) (10) provided the enantiomerically enriched methyleneacyclop propane (S)-24 on multi-gram scale. Ister aminolysis with the lithium salt of 26 gave the vinlylogous imide 27 in 80% yield and 87:13 e.r. (Scheme 8). Deprotonation of 27 with NaHMDS in THF at –78 to –50 °C formed the corresponding sodium enolate, which was trapped with TBSCl to give the silyl enol ether intermediate 28. When heated at 95 °C in THF in the micro-
wave reactor, this diene underwent the intramolecular strain-promoted Diels–Alder (IMDAMC) reaction, and TBAF cleavage of the product silyl enol ether formed the desired trans-adduct 30 in 66% yield along with the cis-adduct 29 in 15% yield. These two diastereomers were readily separated chromatographically. Dehydrogenation of 30 under modified Diao–Stahl conditions\textsuperscript{14} with Pd(TFA)\textsubscript{2} and DMSO in AcOH under an atmosphere of oxygen at 55 °C gave the corresponding enone 31 in 66% as a single regioisomer. Interestingly, dehydrogenation of the epimer 29 under these conditions provided the opposite enone regioisomer 32 stereospecifically in 56% yield. This complete switch in regioselectivity for the cis- and trans-diastereomers 29 and 30 parallels results obtained for the enolization of cis- and trans-2-decalones.\textsuperscript{22} The configuration at the decalin ring junction governs the regioselectivity of enolization process due to torsional strain effects. The torsional strain that was proposed to govern the regiochemistry of enolization in cis- and trans-decalones has also been investigated in greater detail in relevant cis- and trans-oc-talains.\textsuperscript{22b,23}

Enone 31 was obtained as a crystalline solid, and its enantiomeric ratio could be further enriched by recrystallization from 87:13 to yield product with >99% e.r. Chiral SFC analysis was used to evaluate each batch for enantiomeric purity.

For the completion of the total synthesis, stannane 34 was treated with n-BuLi at low temperature and converted into the corresponding lithium carbamion (Scheme 9). Addition of enone 31 to the reaction mixture delivered two diastereomeric allylic alcohols, which could be separated by chromatography on silica gel to give α-alcohol α-35 and β-alcohol β-35 in 41% and 32% yield, respectively. The intramolecular Diels–Alder (IMDAF) reaction of α-35 (bearing a pseudo-equatorial hydroxy group) at 135 °C in a sealed tube was followed by spontaneous aromatization and cleavage of the Tempoc protecting group under the reaction conditions to form indole 36. The stereoisomeric alcohol β-35 was inert under these conditions, quite likely due to steric strain in the transition state that requires a pseudo-axial position of the substituent bearing the furan ring. Finally, lactam reduction led to (+)-cycloclavine in 34% yield over two steps from α-35. Overall, the synthesis of the natural enantiomer was accomplished in 8 steps and 4% yield. The specific rotation of the synthetic material was determined

to be +61.4 (c 0.2, CHCl3), which was consistent with the literature value +63 (c 1, CHCl3). Mass spectra, IR, 1H, and 13C NMR data were also consistent with the previously reported data for the natural product as well as its enantiomer.4,11

In contrast to the vast literature on lysergic acid derivatives, relatively little is known about the pharmaceutical potential of clavine ergot alkaloids.2b Lysergic acid derivatives, most notably lysergic acid diethylamide (LSD) have significant hallucinogenic properties that can interfere with their therapeutic potential. Most of these effects are thought to be mediated through agonist action at the 5-hydroxytryptamine receptor 2A, 5-HT2A. In the tailwind of the rapidly expanding medical uses of cannabinoids, the mushroom metabolite psilocybin, and even LSD, are now moving to the forefront of clinical research on the management of mental health, anxiety, neurodegeneration, and substance-use disorders.24 It would appear that more fundamental research on efficacy, tolerability, and safety of serotonergic psychedelics is highly warranted.

It is well known that binding of lysergic acid derivatives to brain membrane receptors is stereospecific, since L-LSD, the psychotropically inactive enantiomer of LSD, is ca. 1000 times weaker as a brain membrane receptor radioligand displacing agent,25 and l-LSD as well as the other diastereomers, D-iso-lysergic acid diethylamide (iso-LSD) and l-iso-lysergic acid diethylamide (l-iso-LSD), show no psychic effects in humans up to a dose of 0.5 mg, which corresponds to a 20-fold increase over a still distinctly active D-LSD dose.26 Having gained ready synthetic access to both natural (+)-cycloclavine and its unnatural enantiomer (–)-cycloclavine,11 we were therefore interested to determine the receptor profiles of both compounds, and compare them to other serotonergic agents.

For an initial survey, we selected 13 pertinent CNS receptors and profiled both enantiomers at 10 nM concentration (Table 2). Compound binding was calculated as a percent inhibition of a radioactively labeled ligand specific for each target. As a group, the cycloclavines were more selective in this receptor panel than D-LSD,27,28 the bioactive LSD stereoisomer. D-LSD was active at the adrenergic a1 and histamine H1 receptors (Table 2, entries 1 and 6), whereas both

cycloclavines were moderately active at the opiate κ receptor (entry 10). Neither ergot chemotype showed significant activity at GABA_, muscarinic M_2 and M_3, and nicotinic acetylcholine alpha beta receptors (entries 5, 7, 8, and 9). We were unable to find LSD data on orexin OX_1, but cycloclavine did not perturb radioligand binding at this site at a 10 μM concentration (entry 11).

Significant differences between (+)- and (−)-cycloclavine revealed themselves in the dopamine D_1, D_2L, and D_3 monoamine receptor family (Table 2, entries 2–4). In close analogy to D-LSD, natural (+)-cycloclavine maintained strong affinity to these receptors, which stimulate cognitive and motor functions. (−)-Cycloclavine showed comparatively moderate activity at the dopamine D_3 receptor at 10 μM concentration, but fell below the threshold of 50% inhibition at 1 μM, whereas (+)-cycloclavine still maintained significant binding at this concentration (entry 4). A less prominent but still distinctive stereospecificity was observed at the serotonin 5-HT_2A and 5-HT_2C receptors (entries 12 and 13). Natural (+)-cycloclavine had very potent binding properties at both 10 and 1 μM, whereas (−)-cycloclavine tailed off at 1 μM. Serotonin receptors regulate a plethora of behavioral responses, from aggression, anxiety, appetite, to learning, memory, sleep, and even aging. D-LSD is one of the most potent agonists at 5-HT_2A receptor and the affinity at the 5-HT_2A and possibly the 5-HT_2C receptors versus the 5-HT_1A receptor correlates with the mental effects of psychedelics in humans. In view of this interesting stereospecificity, and the significance of 5-HT receptors to human behavior, we decided to pursue additional studies on 5-HT subtypes (Table 3).

The purpose of our second generation functional assays on human 5-HT receptors was to determine effective concentrations EC_50 or inhibitory constants (Ki) for (+)-cycloclavine and (−)-cycloclavine. Cellular agonist effects were calculated as a percentage of a control response to a validated reference for each target, and cellular antagonist effect was calculated as percent inhibition of a validated control agonist response for each target. In addition to D-LSD, we selected N,N-dimethyltryptamine (DMT) and psilocin as two relevant reference compounds. DMT is the only known endogenous N,N-dimethylated trace amine in mammals, and a prominent component in the sacramental tea ayahuasca. Its psychopharmacology has recently been compared to so-called ‘near-death experiences’. Psilocin is the pharmacologically active agent after ingestion of the prodrug psilocybin present in some species of psilocybin mushrooms. Psilocybin is currently clinically investigated as a treatment for anxiety and depression in cancer care, as well as for enhancement of cognitive flexibility and creativity.

As suggested by the preliminary assays, (+)-cycloclavine provided considerably more potent at the 5-HT_1A receptor than (−)-cycloclavine with an activation potency EC_50 = 0.14 μM versus ~5 μM for (−)-cycloclavine (Table 3, entry 1). Both stereoisomers are poor activators at 5-HT_2A, suggesting that hallucinogenic or strongly euphoric effects in humans might be limited in comparison to D-LSD, even though (+)-cycloclavine displays its most potent activation potential EC_50 = 16 nM at 5-HT_2C, a receptor that is thought to contribute to the observed mental effects of psychedelic drugs (entries 2 and 4). With the exception of DMT, which has only moderate potency, none of the tested agents activated 5-HT_2B, a 5-HT receptor subtype that has been associated with cardiotoxicity. Overall, the 5-HT profile of (+)-cycloclavine closely mirrors that of psilocin, and to a lesser extent, that of DMT. It is substantially different from D-LSD, a property that we believe bodes well for future therapeutic investigations of this compound class.

The unusual activity on the opioid κ receptor, and the relative similarity to psilocin and DMT in the 5-HT panel inspired us to also evaluate the activity of cycloclavines in the sigma-1 assay, a receptor that was originally mischaracterized as an opioid receptor and has now been implicated in neuroinflammation and neuroprotection. DMT was identified as an endogenous sigma-1 receptor regulator. Surprisingly, while (+)-cycloclavine was inactive, the unnatural (−)-cycloclavine was determined to have a Ki = 8.3 μM for

the inhibition of the binding of the radiolabeled agonist haloperidol to sigma-1, and therefore found to be very similar to DMT \(K_i = 5.2 \mu M\) (Table 3, entry 5). To the best of our knowledge, this is the first time that stereospecific binding of ergot alkaloids to a sigma receptor has been observed, and, accordingly, it is feasible to consider (–)-cycloclavine as a potential lead structure for sigma receptor modulator design.

In conclusion, we have successfully completed a total synthesis of natural (–)-cycloclavine, featuring an optimization of the catalyst for the asymmetric cyclopropanation of allene with an active ester diazopropanoate, a regiospecific Pd-catalyzed ketone dehydrogenation to the enone, and two intramolecular Diels–Alder reactions for indole/indoline annulations. Furthermore, we have characterized the binding effects of (–)- and (+)-cycloclavine against 16 CNS receptors, and discovered significant stereospecificity properties. (+)-Cycloclavine has at least 10-fold higher potency at the serotonin 5-HT\(_2C\) receptor than at any of the other tested receptors, making it one of the most selective tryptamines discovered to date. Furthermore, the receptor subtype profile of (–)-cycloclavine resembles that of the clinically validated mushroom metabolite psilocin more closely than the related psychedelics LSD and DMT. Finally, we determined that the unnatural (–)-cycloclavine has considerably lower affinities at all 5-HT receptors than (+)-cycloclavine, but is quite active at the sigma-1 receptor, a property that it shares with the endogenous sigma-1 ligand DMT. We suggest that these results, in combination with the excellent synthetic tractability of the cycloclavine scaffold, encourage future research on the medicinal chemistry of clavine alkaloids.

All glassware were dried in an oven at 140 °C for at least 2 h prior to use. All air and moisture-sensitive reactions were performed under a dry \(N_2\) atmosphere. Reactions carried out at 0 °C employed an ice bath and reactions carried out at –78 °C employed a dry ice/acetone bath. THF and Et\(_2\)O were distilled over Na/benzophenone ketyl; Et\(_3\)N, CH\(_2\)Cl\(_2\), and toluene were distilled from CaH\(_2\). All other materials were obtained from commercial sources and used as received. Microwave reactions were performed using a Biotage Initiator or an Anton Paar Monowave 300 reactor in glass microwave vials (cap sealed) with an oven-dried flask topped with a Dean–Stark apparatus and condenser was charged sequentially with (–)-cycloclavine \((R)-18; 0.500 g, 3.77 mmol\), tetrabromophthalallic anhydride \((17; 1.79 g, 3.77 mmol)\), anhyd toluene \((10 \text{ mL})\), and NEt\(_3\) \((0.0536 \text{ mL}, 0.377 \text{ mmol})\). The resulting heterogeneous mixture was heated at reflux while the solvent was removed at a rate of ca. 1 mL/h. The solution was cooled to r.t. and treated withaq 5% HCl \((6 \text{ mL})\) and EtoAc \((15 \text{ mL})\). The aqueous layer was extracted with EtoAc \((6 \text{ mL})\) and the combined organic layers were dried \((\text{Na}_2\text{SO}_4}\) and concentrated to give N-tetrabromophthalalloyl-(R)-tert-leucine as a white solid; yield: 2.11 g (97%); \(\delta_{	ext{H}}^\text{C} 20 +22.3 \text{ (c 0.40, EtOH)}\).

\(^{1}H\) NMR \(300 \text{ MHz, acetone-}d_6\): \(\delta = 4.68 \text{ (s, 1 H), 1.19 \text{ (s, 9 H)}}\). The experimental data were consistent with the literature-reported data for the enantiomer.

N-Tetrabromophthalalloyl-(R)-tert-leucine

An oven-dried flask topped with a Dean–Stark apparatus and condenser was charged sequentially with (–)-cycloclavine \((R)-18; 0.130 g, 0.294 \text{ mmol}\), N-tetrabromophthalalloyl-(R)-tert-leucine \((0.933 g, 1.62 \text{ mmol})\), and a mixture of chlorobenzene and \(\text{MeCN} \((9:1, 13 \text{ mL})\)\). The resulting dark purple solution was heated at reflux while the solvent was removed at a rate of ca. 1 mL/h over 5 h, during which time the solution turned emerald green. After 5 h, the reaction mixture was cooled to r.t. and treated sequentially with tolune \((40 \text{ mL})\) and sat. aq \(\text{NaHCO}_3\) \((40 \text{ mL})\). The organic layer was washed with \(\text{NaHCO}_3\) \((40 \text{ mL})\), brine \((40 \text{ mL})\), filtered, and dried \((\text{Na}_2\text{SO}_4}\) to provide \(10 \text{ (0.555 g, 75\%)}\) as a green solid, which was used directly without further purification.

\(^{1}H\) NMR \(300 \text{ MHz, benzene-d}_6\): \(\delta = 5.37 \text{ (s, 4 H)}\). The experimental data were consistent with the literature-reported data for the enantiomer.

4,7-Diphenyl-3a,4,7,7a-tetrahydroisobenzofuran-1,3-dione

A clear, yellow solution of butadiene \(19 \text{ (2.0 g, 9.6 mmol) and maleic anhydride 20 \text{ (1.1 g, 11 mmol) in xylene (25 mL) was heated at 140 °C for 16 h. After this time, the reaction was cooled to 0 °C and the resulting precipitate was filtered to afford the Diels–Alder adduct as a white solid; yield: 2.29 g (78\%)}\).

\(^{1}H\) NMR \(500 \text{ MHz, CDCl}_3\): \(\delta = 7.43 \text{ (app t, } J = 7.3 \text{ Hz, 4 H), 7.39–7.36 (m, 6 H), 6.56 \text{ (s, 2 H), 3.84 (d, } J = 4.0 \text{ Hz, 2 H), 3.74 (dd, } J = 4.5, 2.0 \text{ Hz, 2 H)}}\). The experimental data were consistent with the literature-reported data.

4,7-Diphenylisobenzofuran-1,3-dione

A red solution of 4,7-diphenyl-3a,4,7,7a-tetrahydroisobenzofuran-1,3-dione \((1.0 g, 3.3 \text{ mmol})\) and \(\text{DDQ} \(1.5 g, 6.6 \text{ mmol}\) in toluene \((10 \text{ mL})\) was heated at 110 °C for 17 h. The reaction mixture was concent -
treated and filtered, and the solid was washed with EtOH to provide crude 21 (0.832 g, 84%) as a light pink solid that was used without further purification.

1H NMR (300 MHz, CDCl3): δ = 7.85 (s, 2 H), 7.61–7.57 (m, 4 H), 7.54–7.51 (m, 6 H).

The experimental data were consistent with the literature-reported data.39

(5R)-2-(1,3-Dioxo-4,7-diphenylisooindolin-2-yl)-3,3-dimethylbutanoic acid (22)

An oven-dried microwave vial was charged sequentially with 4,7-diphenylisooenzofuran-1,3-dione (21: 0.300 g, 1.00 mmol), (S)-tert-leucine (0.199 g, 1.50 mmol), and NEt3 (0.0283 mL, 0.200 mmol), and the resulting homogeneous brown solution was heated at reflux for 19 h. The solution was cooled to r.t., and extracted with aq 5% HCl and EtOAc. The aqueous layer was back-extracted with EtOAc (3 ×), and the resulting heterogeneous brown solution was heated at reflux for 5 h. The crude product was purified by chromatography on SiO2 (0–2% acetone/CH2Cl2) to deliver a green residue, which was recrystallized from CH2Cl2/CH3CN (1:1) as a white solid: mp = 130–131.5 °C (from CH2Cl2/CH3CN (1:1)); [α]D20 = +4.1 (c 0.17, CHCl3).

IR (ATR): 3063, 2926, 1770, 1710, 1603, 1505, 1475, 1382, 1164, 903, 752, 698 cm–1.

1H NMR (300 MHz, CDCl3): δ = 7.67 (s, 2 H), 7.56 (app dd, J = 7.6, 1.9 Hz, 4 H), 7.52–7.45 (m, 6 H), 4.68 (s, 1 H), 1.14 (s, 9 H).

HRMS (ESI+): m/z calcd for C62H52NO6: 955.3568; found: 955.3570.

Asymmetric Cyclopropanation of Allene; General Procedure (Table 1)

Pentafluorophenyl (R)-1-Methyl-2-methylene cyclopropane-1-carboxylate [(R)-24]41

An oven-dried three-necked flask was charged with the respective catalyst (0.0056 mmol) and hexanes or CH2Cl2 (2.8 mL), and the resulting green solution was cooled to –78 °C and treated dropwise with an excess of condensed gaseous allene (23: ca. 14 mmol). The reaction mixture was then treated with a solution of pentafluorophenyl 2-diazopropanoate (4: 0.56 mmol) in hexanes or CH2Cl2 (1.7 mL) via syringe pump at a rate of 1 mL/h. After the addition was complete, the mixture was allowed to warm to r.t. The solution was concentrated under reduced pressure and the resulting residue was purified by chromatography on SiO2 (0–2% EtOAc/hexanes) to provide methylene cyclopropane (R)-24.

1H NMR (400 MHz, CD2Cl2): δ = 5.64 (t, J = 2.8 Hz, 1 H), 5.56 (t, J = 2.2 Hz, 1 H), 2.30 (dt, J = 9.2, 2.5 Hz, 1 H), 1.63 (dt, J = 9.2, 2.4 Hz, 1 H), 1.51 (s, 3 H).

(P,R)-N1-Methyl-2-methylene-N-(3-oxobut-1-en-1-yl)cyclopropane-1-carboxamide [(R)-27]41

An oven-dried flask charged with vinylogous amide 26 (0.0178 g, 0.18 mmol, 1.0 equiv) was evacuated and backfilled with N2 (1 atm). Freshly distilled THF (0.6 mL) was added and the resulting solution was cooled to –78 °C and treated dropwise with n-ButLi (2.29 M solution in hexanes, 0.082 mL, 0.19 mmol, 1.05 equiv). The resulting clear, pale yellow solution was stirred for 5 min at –78 °C, then treated with a solution of ester (R)-24 (0.053 g, 0.19 mmol, 1.05 equiv) in THF (1 mL). The resulting bright yellow solution was treated with DMAP (0.023 g, 0.19 mmol, 0.1 equiv) and stirred for 10 min at –78 °C. The cold bath was removed and the reaction mixture was allowed to warm to r.t. The reaction was quenched with sat. aq NaHCO3. After addition of EtOAc, the aqueous layer was extracted with EtOAc (3 ×) and the combined organic layers were dried (Na2SO4), filtered, and concentrated. The resulting residue was purified by chromatography on SiO2 (0–20% acetone/CH2Cl2) to provide the carboxylic acid 27 as a pale yellow oil; yield: 28 mg (80%)

1H NMR (300 MHz, CDCl3): δ = 5.64 (t, J = 12.8 Hz, 1 H), 5.56 (t, J = 2.2 Hz, 1 H), 2.30 (dt, J = 9.2, 2.5 Hz, 1 H), 1.63 (dt, J = 9.2, 2.4 Hz, 1 H), 1.51 (s, 3 H).

SFC conditions for enantiomer separation: Chiralpak-IC semi-prep column (250 × 10 mm), gradient elution: 5-15% i-ProH, 7 mL/min, 254 nm detection, P = 100 bar.

Pentafluorophenyl (S)-1-Methyl-2-methylene cyclopropane-1-carboxylate [(S)-24] (Table 1, entry 3)

An oven-dried three-necked flask fitted with a N2 inlet, a dry-ice condenser, and a septum was charged with Rh2(OAc)4 (0.016 g, 0.036 mmol), and chlorobenzene (0.5 mL), and the resulting green solution was cooled to –78 °C and treated dropwise with an excess of condensed gaseous allene (23: ca. 65 drops, 5.14 g, 5.52 mmol). The reaction mixture was then treated with a solution of pentafluorophenyl 2-diazopropanoate (4: 6.00 g, 22.6 mmol) in CH2Cl2 (12 mL) via syringe pump at a rate of ca. 2 mL/h. After the addition was complete, the mixture was allowed to stir at –78 °C for 1 h before warming to r.t. The resulting green residue was purified by chromatography on SiO2 (0–1% EtOAc/hexanes) to afford methylene cyclopropane (S)-24 as a clear and pale yellow oil; yield: 5.41 g (86%); [α]D20 = +10.6 (c 0.17, CHCl3).
1H NMR (500 MHz, CDCl₃): δ = 5.64 (app t, J = 2.8 Hz, 1 H), 5.56 (app t, J = 2.3 Hz, 1 H), 2.30 (dt, J = 9.5, 2.5 Hz, 1 H), 1.63 (dt, J = 9.2, 2.4 Hz, 1 H), 1.51 (s, 3 H).

HRMS (ESI+): m/z calcld for C₂₇H₂₃F₄O₂ (M + H)⁺: 494.1175; found: 494.1178.

All other experimental data were consistent with the reported data for the enantiomer.11

(S,E)-1-Methyl-2-methylene-N-(3-oxobut-1-en-1-yl)cycloprop-1-ene-carboxamide ([S]-27)

An oven-dried round bottomed flask was charged with vinylogous amide 26 (2.77 g, 27.9 mmol) and evaporated and backfilled with N₂ (3 ×). Distilled THF (93 mL) was added and the resulting solution was cooled to −78 °C and treated dropwise with n-BuLi (11.7 mL, 2.5 M solution in hexanes, 29.3 mmol). The mixture was stirred for 5 min at −78 °C, then treated dropwise with a solution of pentafluorophenyl (S)-1-methyl-2-methylenecycloprop-1-ene-carboxylate ([S]-24) 28.15 g, 29.3 mmol) in THF (15 mL). The reaction mixture was treated with DMAP (0.0341 g, 0.279 mmol) and stirred for 10 min at −78 °C. The cold bath was removed and the solution was allowed to warm to r.t., and quenched with sat. aq NaHCO₃ and EtOAc. The aqueous layer was treated with a solution of F₂SO₄ and anhyd THF (150 mL) under an atmosphere of O₂ (balloon). After stirring at 55 °C overnight, ketone was allowed to stir for a further 5 min at −78 °C before the cold bath was removed, and the solution allowed to reach r.t.

1H NMR (500 MHz, CDCl₃): δ = 8.37 (d, J = 14.0 Hz, 1 H), 5.73 (d, J = 13.5 Hz,1 H), 5.71 (app t, J = 2.8 Hz, 1 H), 5.53 (s, 1 H), 3.15 (s, 3 H), 2.29 (s, 3 H), 1.80 (dt, J = 9.8, 2.4 Hz, 1 H), 1.50 (s, 3 H), 1.33 (dt, J = 9.7, 2.4 Hz, 1 H).

HRMS (ESI+): m/z calcld for C₁₁H₁₀NO₂ (M + H)⁺: 194.1176; found: 194.1175.

(1aS,3aR,7aR)-1a,3-Dimethylhexahydro-2H-cyclopenta[c]indole-2,5(3H)-dione (30) and (1aS,3aS,7aS)-1a,3-Dimethylhexahydro-2H-cyclopenta[c]indole-2,5(3H)-dione (29)

An oven-dried flask was charged with NaHMDS (2.50 g, 12.9 mmol) and anhyd THF (150 mL) under an atmosphere of N₂. The resulting clear, orange solution was allowed to warm to r.t., and anhyd THF (150 mL) under an atmosphere of N₂. After stirring at 55 °C overnight, ketone was allowed to stir for a further 5 min at −78 °C before the cold bath was removed, and the solution allowed to reach r.t.

1H NMR of an aliquot (CDCl₃) indicated conversion into enol ether 28.

1H NMR (300 MHz, CDCl₃): δ = 7.65 (d, J = 13.5 Hz, 1 H), 5.67 (app s, 1 H), 5.52 (d, J = 13.8 Hz, 1 H), 5.45 (app s, 1 H), 4.23 (s, 2 H), 3.13 (br s, 3 H), 1.73 (dt, J = 9.6, 2.1 Hz, 1 H), 1.47 (s, 3 H), 1.25 (dt, J = 9.4, 2.2 Hz, 1 H), 1.00 (s, 3 H), 0.25 (s, 3 H), 0.24 (s, 3 H).

The mixture was concentrated and directly subjected without purification to the next reaction. A solution of crude amide 28 (assumed 3.98 g, 12.9 mmol) in THF (28 mL, 3.5 mL × 8 batches) was heated under microwave irradiation at 95 °C for 30 min, then concentrated to deliver the crude Diels–Alder adducts (assumed 3.98 g, 12.9 mmol) as an orange oil that was used directly in the next conversion. The crude enol ether adducts (assumed 3.98 g, 12.9 mmol) were immediately dissolved in THF (130 mL), treated dropwise with TBAF (12.9 mL, 1 M solution in THF, 12.9 mmol) and stirred at r.t. for 30 min. The reaction mixture was filtered through a pad of Florisil (washed with EtOAc and concentrated. The resulting residue was purified by chromatography on SiO₂ (20% EtOAc/hexanes to elute recovered starting material, then 50–70% EtOAc/hexanes to elute the trans-diastereomer 30, then 90–100% EtOAc/hexanes to elute the cis-diastereomer 29) to provide trans-ketone 30 as a pale yellow solid (1.64 g, 66%) and cis-ketone 29 as a yellow oil (0.371 g, 15%).

30 [a]Dθ −10.43 (c 0.93 CHCl₃).

1H NMR (400 MHz, CDCl₃): δ = 3.41 (app d, J = 12.8, 4.0 Hz, 1 H), 2.80 (app dd, J = 13.6, 4.0, 1.6 Hz, 1 H), 2.09 (ddt, J = 15.5, 4.8, 1.6 Hz, 1 H), 2.66 (s, 3 H), 2.54 (app d, J = 15.4, 12.2, 7.2 Hz, 1 H), 2.35 (app t, J = 13.4 Hz, 1 H), 2.13 (ddd, J = 12.6, 5.0, 1.4 Hz, 1 H), 1.72 (dd, J = 13.1, 7.3, 1.9 Hz, 1 H), 1.38 (s, 3 H), 0.95 (d, J = 3.6 Hz, 1 H), 0.66 (d, J = 4.0 Hz, 1 H).

HRMS (ESI+): m/z calcld for C₁₁H₁₀NO₂ (M + H)⁺: 194.1176; found: 194.1179.

All other experimental data were consistent with the reported data for the enantiomer.11

29 [a]Dθ +11.0 (c 0.15 CHCl₃).

1H NMR (300 MHz, CDCl₃): δ = 3.73 (app t, J = 6.5 Hz, 1 H), 2.84 (app dd, J = 15.0, 6.0 Hz, 1 H), 2.72 (s, 3 H), 2.53–2.25 (m, 4 H), 1.83 (dt, J = 14.2, 5.2 Hz, 1 H), 1.34 (s, 3 H), 0.93 (d, J = 4.5 Hz, 1 H), 0.84 (d, J = 4.5 Hz, 1 H).

HRMS (ESI+): m/z calcld for C₁₁H₁₀NO₂ (M + H)⁺: 194.1176; found: 194.1178.

Enantiomeric Enrichment by Recrystallization of Enone 31; Typical Procedure

Enone 31 (0.110 g, 0.573 mmol) was dissolved in boiling MTBE (9.5 mL) and 1,2-dichloroethane (0.4 mL) and the solution was allowed to cool to r.t., and kept overnight at −20 °C. The mother liquor was removed via pipette transfer and the white needle-shaped crystals were washed with MTBE (2 ×) and placed under vacuum to remove trace solvents. The first recrystallization provided compound of >99.5:0.5 e.r. by chiral SFC analysis; a 95.4:4.6 e.r. was achieved in the second recrystallization, and the third recrystallization led to 98:2 e.r. to deliver a combined yield of enone 31 (0.0654 g, 60%, 69% of theoretical maximum) as a white crystalline solid. Only combined samples with e.r. >97.5:2.5 were carried on in the subsequent reaction; [a]Dθ + 11.1 (c 0.484, CHCl₃).

An oven-dried 3-necked 25 mL flask fitted with two stoppers and N2 using a liquid N2/Et2O bath, and treated with a solution of enone was maintained between –67.4 and –74.5 °C, then cooled to –93.1 °C which time the temperature rose to –67.4 °C. The resulting clear, yel-
EtOAc (5 ×), and the combined organic layers were dried (Na2SO4), and concentrated. The residue was purified by chromatography on SiO2 (gradient elution 5% acetone/CH2Cl2 to elute recovered starting material enone (3 mg), then alcohol α-35, then 10% acetone/CH2Cl2 was used to elute alcohol β-35) to deliver equatorial alcohol α-35 (0.250 g, 41%) and axial alcohol β-35 (0.196 g, 32%) as white foams.

A solution of α-35 (0.128 g, 0.272 mmol) in anhyd degassed toluene (10 mL) was heated to 135 °C in a sealed tube for 90 h. The reaction mixture was concentrated and filtered through a pad of SiO2, washing with 2–5% acetone/CH3Cl, to provide crude 36 (27 mg, 39%), which was used directly in the next step.

A microwave vial was charged with a solution of crude 36 (0.0270 g, 0.107 mmol) in anhyd THF (1.2 mL) under an atmosphere of N2. The solution was cooled to 0 °C and treated dropwise with LiAlH4 (0.355 mL, 1 M solution in Et2O, 0.535 mmol). The reaction mixture was stirred at reflux in a sealed tube for 16 h, diluted with Et2O, cooled to 0 °C and treated sequentially with H2O (0.020 mL), aq 15% NaOH (0.061 mL), warmed to r.t. and stirred for 15 min.

Anhyd MgSO4 was then added and the solution was stirred rigorously at reflux in a sealed tube for 16 h, diluted with Et2O, cooled to 0 °C and treated sequentially with H2O (0.020 mL), aq 15% NaOH (0.061 mL), warmed to r.t. and stirred for 15 min. Anhyd MgSO4 was then added and the solution was stirred vigorously for 15 min, and filtered through a pad of Celite. The crude residue was purified by chromatography on SiO2 (pre-washed column with 0.1% MeOH/CH2Cl2 with 0.1% NEt3 inlet was charged with Pd(TFA)2 (0.0092 g, 0.027 mmol). The flask was purged and filled with O2, followed by the addition of DMSO (1.9 mL) and stirred at 55 °C under an atmosphere of O2 (balloon) for 20 h then treated with stannane.

A solution of n-BuLi (0.628 mL, 2.5 M solution in hexanes, 1.57 mmol), during 5 min in 0.4 mL portions. The temperature rose to –86 °C during the addition. The reaction mixture was concentrated and filtered through a pad of SiO2, washing with 5% acetone/CH2Cl2 to elute recovered starting material enone (3 mg), then alcohol α-35, then 10% acetone/CH2Cl2 was used to elute alcohol β-35) to deliver equatorial alcohol α-35 (0.250 g, 41%) and axial alcohol β-35 (0.196 g, 32%) as white foams.
