Catalytic Deracemization of Allenes

Significance: Bach and co-workers report an allene deracemization reaction catalyzed by an organic chiral sensitizer under visible light. By using this method, several racemic allenes were converted into enantiomers with yields of ≤100% and ee values of ≤98.5:1.5. DFT calculations are also provided to support the proposed mechanistic description.

Comment: Light-driven deracemization of chiral compounds might be implicated in the origin of early-stage chirality. The present unprecedented discovery presents an example to support this hypothesis. With different substrate classes, solutions to generate chiral centers might be possible in cases where thermally controlled catalytic deracemizations are entropically disfavored.
