**Nanomolar Inhibitor of *Trypanosoma brucei* Trypanothione Reductase**

**Significance:** The parasitic protozoa responsible for trypanosomiasis, Chagas’ disease, and leishmaniasis require the reduction of trypanothione disulfide to trypanothione, which the parasites use in several essential processes. Target molecule N is the strongest competitive inhibitor in vitro of trypanothione reductase from *Trypanosoma cruzi* reported to date.

**Comment:** Note the construction of highly hindered amine E by nucleophilic substitution of benzotriazole from N,N-acetal B by the organomagnesium reagent D.
