We read the publication on “Does the Urinary Calcium/Citrate (UCa/UCi) Ratio Add to the Diagnostic Work-up of Children at Risk of Kidney Stones?” with a great interest. Lee et al noted in the article “UCa/UCi rather than UCi/UCr may be more predictive in the clinical setting when evaluating for nephrolithiasis.”¹ The result in this report is concordant with the previous publication by DeFoor et al.² Nevertheless, there is an important consideration regarding the urine calcium and citrate measurement. The sexual variation should also be mentioned. For urine calcium, there is no sexual variation; however, a sexual variation is reported for urine citrate.³ This variation should be kept in mind while interpreting the UCa/UCi ratio in pediatric patients.

Conflict of Interest
None declared.
