Abstract

The accurate examination of oral cavity may acknowledge findings that demonstrate the presence of underlying systemic, which helps in earlier diagnosis as well as treatment. The oral tissues are accountable to damage as a disease consequence that primarily affects other body systems. Various systemic diseases show oral manifestation. Some of these oral conditions include oral ulcers, caries, dry mouth, gingival bleeding, and gingival hypertrophy. This review article is prepared to make general physicians as well as dentist aware about systemic disorders or conditions that show dental or oral manifestation.

Keywords
► oral manifestations
► systemic diseases
► disorders

Introduction

Inadequate oral health is an utmost problem worldwide. There are many investigations done to check the relationship between various systemic diseases and oral health. Various epidemiology-based studies have related the bad oral conditions to different conditions such as cardiovascular diseases, respiratory diseases, adverse pregnancy outcomes, stroke, malignant diseases, obesity, and rheumatoid arthritis.¹⁻⁵

Oral inspection or investigation shows clinical features of various diseases such as hematologic conditions, endocrinopathies, immunologic diseases, nutritional disorder, and systemic infections.⁶ Mouth may be considered as a reflector of diseases or health. Various systemic diseases show their oral manifestation.⁷

Various Systemic Diseases with Their Oral Manifestation

Pulmonary Disorder and Oral Manifestation
Chronic Obstructive Pulmonary Diseases
Smoking is considered as a significant risk factor for chronic obstructive pulmonary disease (COPD) as well as periodontal abnormalities. As per the study conducted by Katancik et al in 2005, a remarkable relationship between periodontal disorders and airway obstruction was noticed.⁸ Another study was conducted by Prasanna in 2011 to check the relationship between periodontal diseases and COPD. He proposed that periodontitis is important risk factors for COPD.⁹

In the year 2014, Öztekin et al in their study noted that there is association between the periodontal diseases and COPD.¹⁰
Numb chin syndrome may be observed in his study that a patient who is suffering from ulcerative colitis shows oral manifestations including papules, ulcers, and edema with differentiation from gingiva, lips, and vestibular sulci.

Pellicer et al. observed in their study that patients having ulcerative colitis exhibit increased possibility of development of enamel defects mainly enamel hypoplasia. Because of the celiac disease, there is decreased rate of flow of saliva that in turn results in dry mouth.

Elahi et al. observed in their study that the children with celiac disease have increased risk of enamel defects and these enamel defects are responsible for occurrence of caries.

Celiac diseases show various oral manifestations. Patients having celiac diseases exhibit increased possibility of development of enamel defects mainly enamel hypoplasia. Because of the celiac disease, there is decreased rate of flow of saliva that in turn results in dry mouth.

Avşar and Kalayci observed in their study that the children with celiac disease have increased risk of enamel defects and these enamel defects are responsible for occurrence of caries.

**Gastroesophageal Reflux Diseases**

Di Fede et al. noted in their study the significant relationship between gastroesophageal reflux disease (GERD) and erythema of palatal mucosa as well as uvula. Wang et al. in their study observed a significant relationship between GERD and oral erosions and dental erosions.

**Hematologic Disorder and Oral Manifestation**

**Anemia**

Most frequent hematologic disorder is anemia. Iron deficiency anemia shows oral manifestation in the form of mucosal pallor, atrophic glossitis, and angular cheilitis. Sickle cell anemia shows mandibular salmonella osteomyelitis, pulpal necrosis, and mandibular nerve paresthesia as oral manifestations. It also shows enamel hypomineralization, orofacial pain as well as diastema.

**Leukemia**

Leukemia shows various forms of oral manifestations that include petechiae, gingival hypertrophy, ecchymosis, hemorrhage, and mucosal ulcers. Numb chin syndrome may be seen occasionally.

In case of acute myeloid leukemia, most common oral features seen are oral ulceration, gingival bleeding, and gingival hyperplasia. Also, spontaneous bleeding can be seen in palate, gingiva, lips, or tongue. Oral ulcerations can be noted very commonly. In patients who are suffering from acute lymphoblastic leukemia, oral features include gingival bleeding and ecchymoses along with lymphadenopathy that is a persistent sign.

Additionally, in case of chronic lymphocytic leukemia, oral features seen include localized swelling with pain and ulcers. Gingival bleeding as well as purpura can be noted. Some features such as gingival leukemic infiltration and palatal enlargement are linked with chronic lymphocytic leukemia.

**Liver Diseases and Oral Manifestation**

In liver malfunctioning, the oral cavity displays some manifestations in the form of gingivitis, gingival bleeding, mucosal membrane jaundice, petechiae, feter hepaticus, xerostomia, and atrophic tongue. Chronic periodontal disease is the most common disease in these patients.
Some manifestations such as gingivitis, angular cheilitis, and glossitis can be seen in patients suffering from alcoholic hepatitis. A study was conducted by Bagán et al to check the dental status in patients having cirrhosis of liver. They noted the remarkable number of missing teeth and carious teeth in patients with cirrhosis of liver and concluded that substandard dental status was seen.

**Renal Diseases and Oral Manifestation**
Renal diseases may show various oral manifestations. These include mucositis, stomatitis, and glossitis. In renal infection and altered taste sensations, are established because of renal diseases.

In a study done by Martins et al, it was observed that those chronic renal failure patients (children and adolescents) undergoing hemodialysis may present oral manifestations that include delayed tooth eruption, dry mouth, dental stains, and calculus. Koch et al in their study noted that cases of chronic renal failure may influence the development of enamel in primary teeth that result in enamel hypoplasia.

Galili et al in 1991 conducted a study to compare the dental pulp size in chronic renal diseases with healthy controls. They observed the significant relationship between renal diseases and narrowing of pulp in premolar as well as molar teeth. Jaffe et al in their study concluded that children suffering from chronic renal failure shows delay in dental maturation.

**Endocrine Disorders and Oral Manifestation**

**Diabetes Mellitus**
Diabetes mellitus shows number of oral manifestations. The majority of patients suffering from diabetes shows xerostomia because of restricted salivary flow and rise in salivary glucose level. Other factors that contribute to oral manifestations include increased vulnerability to infections, collection of plaque and food debris, and poor healing.

Falk et al in their study have observed the high frequency of dental caries in poorly controlled diabetic patients. Also, these patients show occurrence of loss of periodontal attachment.

**Hyperparathyroidism**
Most common oral manifestations seen in oral cavity include mobility of teeth, loss of bone density, and variations in tooth eruption calcifications of soft tissue. Also, loss of lamina dura with changes in jaw trabecular pattern can be seen.

**Hypoparathyroidism**
Most common manifestations seen in hypoparathyroidism are enamel hypoplasia and delayed eruption. Some teeth show root malformation along with interruption in the dental development and growth. Facial twitching with lip or tongue paresthesia can also occur. Radiographic features, such as wide root canal, large pulp chambers, and thickened lamina dura, are some other oral manifestations.

**Hyperthyroidism**
Variety of oral manifestations are seen in cases of hyperthyroidism. Periodontal diseases, osteoporosis of maxillary, or mandibular portion of jaw increased vulnerability to dental caries and expedited dental growth.

**Hypothyroidism**
Hypothyroidism shows various oral manifestations that appear in the form of dysgeusia, substandard periodontal conditions, enlarged tongue, and delayed healing of wound.

**Conclusion**
The consequence of systemic diseases on oral cavity is well noted and it includes various soft tissue and hard tissue abnormality as well as pathology. Oral manifestation is the first sign of systemic diseases. General physicians and dentist need to be mindful of understanding the oral complaints.
