Abstract Flow synthesis of triptycene was achieved using triple cycloaddition of ynolate to benzyne. Employing the borate-type benzyne precursor, side reactions triggered by the addition of alkyllithium to benzyne were efficiently suppressed under microflow conditions, thus producing triptycene with a higher yield than that obtained under the corresponding batch conditions. Furthermore, ynolate prepared from α,α -dibromoester under microflow conditions was continuously added to the flow reaction with benzyne, which successfully synthesized triptycene in only one minute.

Keywords triptycene, ynolate, benzyne, flow synthesis, cycloadditionborate

Triptycenes are symmetric compounds with three benzene rings fixed by a bicyclo[2.2.2]octatriene bridgehead system.¹ Based on their unique and rigid skeleton, the compounds have been utilized in fields such as host–guest chemistry, supramolecular chemistry, and material chemistry.² Studies have reported several synthetic methods for triptycene synthesis, e.g., the Diels–Alder reaction of anthracenes and benzenes³ or quinones,⁴ the intramolecular Friedel–Crafts reaction,⁵ and the [2+2+2] cycloaddition of alkynes.⁶ Furthermore, we have recently developed a new synthetic method for triptycene based on a triple cycloaddition of one ynolate **1**⁷ to three benzenes **2** (Scheme 1).⁸ This method can be easily performed, where alkyllithium is added to a mixture of ynolate and a benzyne precursor. The yield of triptycene **3** varies from 27–69% when employing fluorobenzene or 3-fluoroanisole as the benzyne precursor. In the cases that resulted in low yields, abundant benzyne byproducts were produced. Generally, short-lived benzenes should be trapped by an excess of arynophiles. However, the triple cycloaddition reaction does not use the excess ynolate because the reaction needs at least three equiva-

lents of benzyne to ynolate. Therefore, it is important to generate benzenes incrementally. Moreover, the generation of benzyne using a strong base, such as alkyl- or aryllithium, competes with the side reactions triggered by the addition of the base to benzyne. Thus, suppression of these side reactions is key to improving the yield but is not easily achieved in a batch system because inefficient mixing causes an uneven distribution of concentration and temperature in the reaction vessel.

Scheme 1 Synthesis of triptycene via triple cycloaddition of ynolate to benzyne

These issues in the batch system could be solved using microflow systems, which have the potential to provide constant reaction parameters, such as reaction temperature, time, and concentration, due to high mixing efficiency and rapid heat transfer.⁹ Furthermore, the rapid diffusion of the reaction mixture helps suppress undesired contact of intermediates or the product with the starting materials and reagents. Therefore, it has been illustrated that the microflow conditions are beneficial in many exothermic reactions via unstable intermediates such as alkyllithium-initi-

ated reactions. For example, Yoshida and co-workers reported that the efficient formation and reaction of benzyne were achieved using microflow systems.¹⁰ We have reported the flow synthesis of ynolate from α,α -dibromoester using alkyllithium^{7d} or lithium naphthalenide and achieving other reactions of ynolates under microflow conditions.¹¹ Based on these results, we envisioned that microflow systems could improve the efficiency of the synthesis of triptycene through the precise control of reaction conditions. Thus, this report details the flow synthesis of triptycene via triple cycloaddition of ynolate and benzyne using flow microreactors.

The investigation began with the reaction using *o*-bromiodobenzene and PhLi for the preparation of benzyne (Table 1).^{10a} The reaction was carried out using a Comet X-01 mixer (Techno Applications Co., Ltd, Tokyo, Japan) as a microreactor. A solution of lithium ynolate **1** was prepared in advance by our method in a batch system.^{7d} In entry 1, a solution of PhLi (0.97 M) and a mixture of ynolate **1** (0.12 M) and benzyne precursor **2** (0.70 M) were pumped into the reactor at a 1.0 mL/min in a ratio of **1**/PhLi = 1:6:8. The solutions were mixed at $-20\text{ }^{\circ}\text{C}$, and the resulting mixture flowed through a tube with 0.8 mL volume, where the residence time was approximately 24 s, into the aqueous HCl solution to quench the reaction. The yield of triptycene **3** was estimated by NMR to be approximately 21%. In entries 2 and 3, the reaction temperature was increased to $0\text{ }^{\circ}\text{C}$ and $22\text{ }^{\circ}\text{C}$, which resulted in higher yields of **3**. When the ratio of **1**/PhLi was changed to 1:8:11 and 1:3:4, the

yields were diminished (entries 4 and 5). The faster flow rates (1.5 mL/min and 2.0 mL/min), with residence times of 16 s and 12 s, were effective, thus synthesizing the product with yields of 33% and 31%, respectively (entries 6 and 7).

For comparison, the reaction was also performed in the batch system under the conditions corresponding to entry 6 in Table 1, and triptycene **3** was obtained with a 31% NMR yield (25% isolated yield), which was slightly less than that obtained in the microflow conditions (Scheme 2). This may indicate that the microflow system improved the efficiency of the triple cycloaddition of ynolate to benzyne. However, we realized that it is not easy to suppress the side reactions under these microflow conditions, because the formation of many byproducts was still observed on the GC-MS analysis of the crude products (see Figure S1 in the Supporting Information). The major byproducts were biphenyls and *o*-terphenyls, which would be formed by the addition of aryllithium intermediates to benzyne. Although this result indicates that benzyne was generated efficiently, most of the benzyne was wasted in the side reactions.

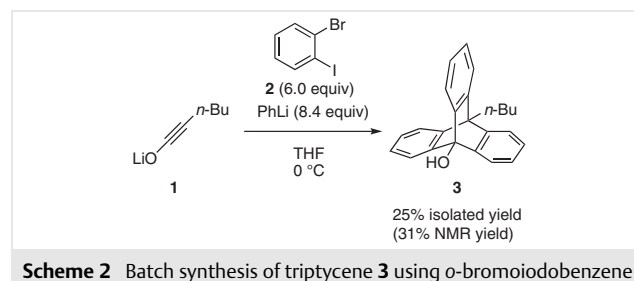

Table 1 Flow Synthesis of Triptycene Using *o*-Bromiodobenzene

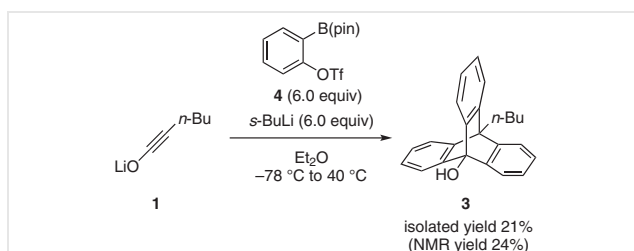

Entry	Concn of 1 (M)	1 / 2 /PhLi ^a	T (°C)	s (mL/min)	t (s)	Yield (%) ^b

Thus, we changed the precursor of benzyne to *o*-(trifluoromethanesulfonyloxy)phenylboronic acid pinacol ester **4** developed by Hosoya and co-workers (Table 2).^{12,13} It has been reported that the treatment of alkyllithium with **4** generates borate complex **5**, which is stable at $0\text{ }^{\circ}\text{C}$ and then converts into benzyne when warmed to room temperature. Based on this, we envisioned that the undesired addition reactions to benzyne could be suppressed using precursor **4** because, by the formation of the borate complex in advance, the coexistence of nucleophilic butyllithium and benzyne can be avoided. Slow generation of benzyne could also be achieved by temperature control of the borate complex solutions in the second step. The microreactor system consisted of two mixers, **A** and **B**. The solutions of precursor **4** and *s*-BuLi were introduced into the microreactor and combined in mixer **A** at $-78\text{ }^{\circ}\text{C}$. The resulting solution of borate complex **5** was mixed with a solution of ynolate **1** in mixer **B** and then passed through the tube maintained at the indicated temperature. In entry 1, the ratio of **1**/**4**/*s*-BuLi was 1:6:6, and the reaction was performed at $23\text{ }^{\circ}\text{C}$ to provide triptycene **3** with a 19% yield. When the reaction temperature was elevated to $40\text{ }^{\circ}\text{C}$ and $60\text{ }^{\circ}\text{C}$, the yield of **3** increased to 33% and 29%, respectively (entries 2 and 3). However, the use of 5 or 8 equivalents of **4** and *s*-BuLi diminished the

yield (entries 4 and 5). In entry 6, the reaction employed a higher concentration of the solutions in comparison with entry 2, which resulted in no influence on the NMR yield and a 31% isolated yield of **3**. It should be emphasized that GC-MS analysis of the crude products indicated considerable suppression of side reactions (see Figure S2 in the Supporting Information). The main byproducts were *o*-bromophenylboronic acid pinacol ester and biphenylene formed via dimerization of benzyne. These results suggest that the almost complete consumption of *s*-BuLi was achieved in the first step, and thus, the competitive addition reactions to benzyne were largely suppressed. Therefore, although the yield was as much as one of the first approach as shown in Table 1, purification of triptycene **3** was much easier to perform in this approach. Furthermore, the batch reaction, which was performed under the conditions corresponding to entry 6 in Table 2, synthesized triptycene **3** with a 21% yield (24% NMR yield, Scheme 3). Thus, the reaction efficiency of the triple cycloaddition reaction was also improved under the microflow conditions probably due to the high mixing efficiency.

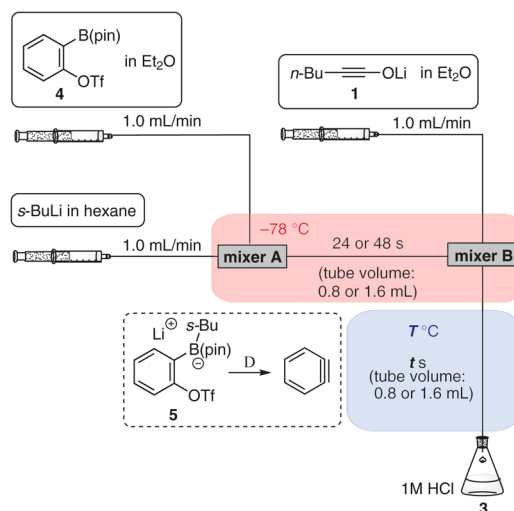

Scheme 3 Batch synthesis of triptycene **3** using borate-type benzyne precursor **4**

Finally, ynolate **1**, prepared under the microflow conditions, was directly employed for the flow synthesis of triptycene (Scheme 4). The solutions of α,α -dibromoester (1.20 M) and lithium naphthalenide (0.25 M) were mixed in mixer **A** at 22 °C to produce ynolate **1**. At the same time, the solutions of benzyne precursor **4** (0.38 M) and *s*-BuLi (0.38 M) were pumped into mixer **B**. These two resulting solutions were then introduced into mixer **C**, and the reaction mixture passed through a tube maintained at 40 °C for 16 s. Triptycene **3** was successfully obtained with a 16% yield judged by the NMR spectra. Although the yield was less than that of the prior flow systems, the current flow system provided advantages, including that the whole reaction was completed in only one minute.

In conclusion, we have developed flow synthesis of triptycene using triple cycloadditions of ynolate-benzyne under microflow conditions. Using Hosoya's benzyne precursor, dramatic suppression of side reactions, and improvement in yield compared with the corresponding batch system was achieved. This can be attributed to the microflow conditions, such as efficient mixing and rapid heat

Scheme 4 Flow synthesis of triptycene, including the preparation of ynolate

transfer. The flow reaction was also performed using yno-
late, which was prepared under microflow conditions, syn-
thesizing the triptycene in only one minute. This is the first
report for flow synthesis of triptycene, as far as we know.
Further improvement of the reaction efficiency is now un-
der investigation in our group.

- (13) **Representative Procedure for the Synthesis of 9-Hydroxyl-
triptycene 3 Using Benzyne Precursor 4**
Solution A
o-(Trifluoromethanesulfonyloxy)arylboronic acid pinacol ester
(**4**, 1.58 g, 4.50 mmol) was dissolved in Et₂O (10.0 mL), and the
resulting solution was put in a syringe.
Solution B
s-BuLi (0.97 M in cyclohexane and hexane) was diluted with
hexane to be 0.45 M solutions, 10.0 mL of which was put in a
syringe.
Solution C
To a solution of ethyl 2,2-dibromohexanoate (227 mg, 0.750
mmol) in Et₂O (3.0 mL), cooled to -78 °C under argon atmo-
sphere, was added dropwise a solution of t-BuLi (1.50 M in pen-
tane, 2.0 mL, 3.0 mmol). The resulting yellow solution was
stirred for 30 min at -78 °C and then for another 30 min at 0 °C.
The resulting colorless solution of ynoate was diluted with Et₂O
to make total volume of 10.0 mL and put in a syringe.
Reaction
A flow microreactor system consisting of two micromixers (**M1**
and **M2**, comet X each) and two microtube reactors (**R1**:
ø = 1000 µm, L = 100 cm, V = 0.8 mL and **R2**: ø = 1000 µm,
L = 100 cm, V = 0.8 mL) was used. **M1**, **M2**, and **R1** were dipped
in a cooling bath at -78 °C, and **R2** was dipped in a warming
bath at 40 °C. Solutions A and B were introduced to **M1** using
syringe pumps in a flow rate of 1.0 mL/min each. The resulting
solution was passed through **R1** and was mixed with solution C
(flow rate: 1.0 mL/min) in **M2**. The resulting solution was then
poured into 1 M HCl. After a steady state was reached, the
product solution was collected for 120 s (corresponding to 0.15
mmol of ynoate solution). The collected mixture was extracted
with CHCl₃. The combined organic phase was washed with
brine, dried over MgSO₄, filtered, and concentrated. The crude
product (24% NMR yield) was purified by silica gel column chro-
matography (hexane-EtOAc = 25:1) to afford compound **3** (15.2
mg, 31%) as a white solid.
Triptycene 3
¹H NMR (600 MHz, CDCl₃): δ = 7.54 (d, J = 6.9 Hz, 3 H), 7.39 (d,
J = 6.9 Hz, 3 H), 7.03–7.08 (m, 6 H), 3.25 (s, 1 H), 2.93 (t, J = 7.6 Hz, 2
H), 2.12–2.17 (m, 2 H), 1.79–1.85 (m, 2 H), 1.16 (t, J = 7.2 Hz, 3 H).
The NMR spectrum was matched with that of our previous report.
