Abstract

Thrombocytopenia is commonly associated with sepsis and infections, which in turn are characterized by a profound immune reaction to the invading pathogen. Platelets are one of the cellular entities that exert considerable immune, antibacterial, and antiviral actions, and are therefore active participants in the host response. Platelets are sensitive to surrounding inflammatory stimuli and contribute to the immune response by multiple mechanisms, including endowing the endothelium with a proinflammatory phenotype, enhancing and amplifying leukocyte recruitment and inflammation, promoting the effector functions of immune cells, and ensuring an optimal adaptive immune response. During infection, pathogens and their products influence the platelet response and can even be toxic. However, platelets are able to sense and engage bacteria and viruses to assist in their removal and destruction. Platelets greatly contribute to host defense by multiple mechanisms, including forming immune complexes and aggregates, shedding their granular content, and internalizing pathogens and subsequently being marked for removal. These processes, and the nature of platelet function in general, cause the platelet to be irreversibly consumed in the execution of its duty. An exaggerated systemic inflammatory response to infection can drive platelet dysfunction, where platelets are inappropriately activated and face immunological destruction. While thrombocytopenia may arise by condition-specific mechanisms that cause an imbalance between platelet production and removal, this review evaluates a generic large-scale mechanism for platelet depletion as a repercussion of its involvement at the nexus of responses to infection.

► thrombocytopenia
► immune response

Infections, both bacterial and viral, are associated with a profound immune response to the infecting pathogen. Platelets are important contributors to the multifaceted response to infection, where they have the ability to modulate various immune cells. Platelets engage the immune system through direct cell-to-cell interaction and through the release of various soluble mediators.1-5 Furthermore, platelets participate in the interaction between pathogens and host defense.6-12 In the absence of platelets, bacteremia, tissue damage, and mortality are greatly enhanced.13-15 Similarly, thrombocytopenia is associated with a dysregulated host response and worse outcomes in sepsis patients.16,17 Platelets are also active participants in the host response to viruses, and have been shown to be protective in viral infections.18-20 Platelets possess receptors that allow them to survey for danger signals from pathogens (pathogen-associated molecular patterns; PAMPs) and cell damage (damage-associated molecular patterns; DAMPs), and trigger hemostatic and

ISSN 0094-6176.
inflammatory responses against bacterial and viral infections.\(^3\,21,22\). During infection, the platelet is activated, mobilized, and actively participates in the resultant hemostatic and inflammatory responses. These signaling processes involve many feedback loops that self-amplify initial activation,\(^23\) and platelets can manifest dysfunction even in cases where no bacteremia is present.\(^10\) These processes are irreversible and undoubtedly lead to consumption of the platelet. Activation of platelets leads to their consumption into aggregates with other platelets, leukocytes, and the endothelium.\(^24\) Platelets with bound antibody are targets of phagocytes, and platelets with a bacterial or viral load are sequestered and also cleared from the circulation. Further, pathogenic compounds induce apoptosis and cytotoxic effects in platelets.\(^25\) In this sense, activated platelets and platelets interacting with pathogens have shortened survival spans and experience increased destruction. The outcome for the patient will be a decrease in normal circulating platelets, and if this manifests widely enough it can be measured as thrombocytopenia.\(^3,25\)

Other mechanisms of platelet decline in infection exist and include the formation of autoantibodies against platelet surface proteins, which leads to clearance of immunoglobulin G (IgG)-coated platelets by the reticuloendothelial system,\(^26,27\) as well as by impaired platelet production in the bone marrow,\(^3,6\) among others.\(^6\) However, a general view of platelet destruction is the simple characteristic that their involvement in thrombotic, hemostatic, immune, and host defense responses is irreversible. Even if platelets are positive contributors to the host response against invading pathogens, they can become dysfunctional, especially in the context of an excessive and unbalanced systemic inflammatory response.\(^16,28\) Indeed, the dysfunctional state of thrombocytopenia is commonly associated with sepsis and infections.\(^3,29–31\)

The focus of the current review is platelets and their role in infection. We will examine the interaction of platelets, their receptors, and secretory product with bacteria and viruses, and discuss how this may contribute to platelet dysfunction and ultimately lead to thrombocytopenia. \(\text{Fig. 1}\) provides the rationale of this review and \(\text{Table 1}\) lists the abbreviations used in this article.

### Platelet and the Immune Response to Infections

A common feature of many infections, both viral and bacterial, is a systemic inflammatory response that involves a dysregulated proinflammatory biomarker presence in the circulation.\(^3,5,32\) These biomarkers may include cytokines (e.g., interleukins [ILs]), tumor necrosis factor [TNF]-\(\alpha\), and interferons) but also molecules originating from bacteria and viruses themselves (e.g., proteases, ribonucleic acid [RNA], and membrane components like lipopolysaccharide [LPS], lipoteichoic acid [LTA], and viral glycoproteins). The presence of such circulating biomarkers has profound agonistic effects on platelets.

Platelets contribute to the thromboinflammatory response through the plethora of membrane and cytosolic molecules that they express and release, which possess hemostatic, immunomodulatory, and inflammatory activity.\(^1–4\) Platelets possess receptors that enable pathogen sensing, and which allow platelets to regulate leukocytes and other cells at the site of infection. During platelet activation, degranulation leads to the release of abundant proinflammatory mediators, which contribute to numerous signaling events.\(^1–5\) Platelets also adhere and aggregate to other platelets and to endothelial cells, leukocytes, and erythrocytes.\(^5,9,24\) This response is also characteristic during bacterial and viral infections, and can be induced by pathogens directly.\(^33\) This section describes the role of platelets in the immune response. See \(\text{Fig. 2}\) for a general overview of platelet receptors and secretory products.

### Platelet–Endothelium Interactions: Endowing a Proinflammatory Phenotype

Endothelial activation markers are raised during infection, and are associated with a thrombotic state.\(^34\) During activation, platelets can bind to the endothelium.\(^24\) This especially occurs upon endothelial damage due to trauma or microbial colonization,\(^35\) as well as in viral infections.\(^36\) Platelets become activated during the adhesion process, and the inflammatory and mitogenic substances that are released alter the chemotactic, adhesive, and proteolytic properties of endothelial cells.\(^37\) Platelet adhesion therefore endows the endothelium with a proinflammatory phenotype.\(^24\) Moreover, platelets that are bound to the endothelium can form a bridging connection with circulating leukocytes.\(^24\) Overall, these mechanisms amplify and facilitate leukocyte recruitment and enhance inflammation. \(\text{Fig. 3}\) provides an overview of the contact between platelets and cells at the vascular wall to emphasize the involvement of platelets in multiple interactions at the vessel wall.

### Platelet–Leukocyte Interactions: Promoting Immune Cell Effector Functions against Pathogens

Interactions between platelets and leukocytes are important for the regulation of the immune response and for the clearance of infectious agents. By binding and activating leukocytes, platelets promote their effector functions. Coordination of

---

\(\text{Fig. 1}\) Layout of the review. During infection, inflammatory stimuli, and the presence of bacteria, viruses and their products mobilize platelets to exert their immune, antibacterial, and antiviral actions. However, these processes can also lead to platelet dysfunction and ultimately depletion.

Platelet Dysfunction and Depletion in Infection

Immune cells by platelets ensures a rapid and targeted host defense response. In a dynamic cross-talk, leukocytes can also release factors that modulate platelet function.

Platelets adhere to phagocytes and deliver signals that enhance the killing of internalized pathogens. Platelets are able to modulate neutrophil responses where they enhance neutrophil phagocytosis in a process involving toll-like receptor (TLR) 2 and P-selectin/P-selectin glycoprotein ligand (PSGL)-1. This was demonstrated for both Aggregatibacter actinomycetemcomitans and Porphyromonas gingivalis.

Platelets can augment the respiratory burst in neutrophils in response to opsonized Escherichia coli and Staphylococcus aureus. Platelet–neutrophil complexes have more activated adhesion molecules, greater phagocytic ability, and greater toxic oxygen metabolites than noncomplexed neutrophils. Activated platelets can also induce superoxide anion release by monocytes and neutrophils through P-selectin. Soluble CD40 ligand (CD40L) further interacts with CD40 and αMβ2 on neutrophils to induce the adhesive functions of neutrophils as well as cause CD40-dependent reactive oxygen species (ROS) generation.

Additionally, the triggering receptor expressed on myeloid cells (TREM)-1 ligand is expressed on platelets and has been shown to induce neutrophil activation, and platelets enhance the neutrophil respiratory burst and release of IL-8 in a TREM-1-specific manner in the presence of LPS. The TREM-1 receptor is an important receptor in the innate immune response as well as in severe sepsis where it amplifies the immune response to microbial products. TREM-1 has also been shown to contribute to neutrophil activation in viral infections.

Furthermore, platelets induce the release of neutrophil extracellular traps (NETs), deoxyribonucleic acid (DNA) covered with various antimicrobial nuclear and granule-derived molecules that allow them to detect danger signals and engage other cells. Moreover, NETs have been shown to induce expression of CD40L on human CD8+ T cells, and protect the host from lethal hemorrhage. Activated platelets can also contribute to immunopathology (e.g., liver damage) by accumulating virus-specific cytotoxic T cells at the site of inflammation in models of acute viral hepatitis. Serotonin released from platelets is vasoactive and can further support viral persistence in the liver by reducing microcirculation, which aggravates virus-induced immunopathology in a model of LCMV-induced hepatitis.

Platelets can further shuttle blood-borne gram-positive bacteria to splenic CD8α+ dendritic cells after the bacterium becomes associated to platelets via glycoprotein (GP)-Ib and...
Platelet interactions at the vascular wall. Platelet activation and adhesion to the vascular wall is facilitated by various receptor interactions with endothelial cells. An inflamed vessel wall will adopt a prothrombotic phenotype and release platelet binding and stimulating agents. The adhesion of platelets activates endothelial cells, and together with potent inflammatory mediators released by platelets induces the expression of integrins, adhesion molecules, and other receptors on the endothelial surface, as well as causes the endothelium to secrete chemokines and other mediators. Platelets similarly bind and activate leukocytes, contributing to leukocyte recruitment to the endothelium. In turn, leukocytes are activated and are able to adhere to the inflamed vessel, with platelets also serving as bridging connections between the endothelium and circulating leukocytes (created with https://biorender.com/). (Adapted from van Gils et al24.) ADP, adenosine diphosphate; GM-CSF, granulocyte-macrophage colony-stimulating factor; ICAM, intercellular adhesion molecule; IL, interleukin; JAM, junction adhesion molecule; MCP, monocyte chemoattractant protein; MMP, matrix metalloproteinase; MT1-MMP, membrane type-1 MMP; PF, platelet factor; PSGL, P-selectin glycoprotein ligand-1; RANTES, regulated on activation, normal T-cell expressed and secreted; ROS, reactive oxygen species; TNSF14(R), tumor necrosis factor superfamily member 14 (receptor); uPA, urokinase-type plasminogen activator; uPAR, urokinase receptor; VCAM, vascular cell adhesion protein; vWF, von Willebrand factor.
complement C3 to balance bacterial clearance with immune induction. Activated platelets also form aggregates with CD16+ inflammatory monocytes and human leukocyte antigen (HLA)-DR+ CD38+ memory T cells in human immunodeficiency virus (HIV) infection.

Platelet-Derived Microparticles: Further Driving the Inflammatory Response

Activated platelets produce microparticles during bacterial63,64 and viral infection65,66 that contain both soluble (e.g., regulated on activation, normal T cell expressed and secreted [RANTES]) and surface mediators (e.g., P-selectin, GPIb, and αIIbβ3), which can exit the vasculature and enter tissues where they are able to activate leukocytes to further drive the inflammatory response.67,68 For example, platelet microparticles enhance the expression of cell adhesion molecules such as leukocyte αMβ2 for monocyte adhesion,69 and can mediate leukocyte activation70 and leukocyte–leukocyte interactions.71 Microparticles promote platelet interaction with the endothelium by acting as a substrate for further platelet binding.72 Further, microparticles can deliver platelet-derived CD40L signals54,73 and activate dendritic cells.74 Platelet microparticles also promote endothelial activation by secreting IL-1β75 and can deliver RANTES to the endothelium for monocyte recruitment.76 Lastly, these microparticles can cause complement activation.77

Fig. 4 Platelet interactions with immune cells. Platelets are important contributors to the multifaceted immune response to infection and have the ability to engage the immune system. Degranulation leads to the surface expression of receptors and the release of abundant proinflammatory mediators that regulate leukocytes at the site of infection. Platelets also modulate leukocytes involved in adaptive immunity. Ultimately, platelets promote the effector functions of immune cells and enable an optimal immune response (created with https://biorender.com/). Platelet Interactions with Bacteria
Platelets are active role players in antimicrobial defense, and exhibit complex interactions with bacteria and viruses due to the variety of platelet receptors involved in pathogen recognition. Platelets are able to recognize, bind, and internalize pathogens to sequester and neutralize the pathogen. This section describes the interactions of platelets with bacteria, which are summarized in Fig. 5.

Platelet Receptors in Bacterial Pathogen Sensing
It has long been known that bacteria can cause platelet aggregation and degranulation. A diverse range of platelet receptors can mediate interactions with bacteria, including αIIbβ3, low-affinity immunoglobulin gamma Fc region receptor II-a (FcγRIIa), GPIb, complement receptors (CRs), and TLRs, either directly or indirectly through bridging molecules. Alternatively, products shed by bacteria may cause a platelet response independently of direct interactions with platelet receptors.

**Fig. 5** Platelet interactions with bacteria. Platelets are able to sense and bind bacteria through a variety of platelet receptors, and various bacterial products stimulate platelets, modulating their function. Platelets typically become activated and aggregate, but bacterial products may exert inhibitory actions or cause platelet destruction. Platelets additionally mediate antimicrobial actions by releasing microbicidal proteins, engulfing bacteria, and interacting with immune cells. These interactions further enhance the immune response and lead to platelet clearance (created with https://biorender.com/). C3, complement component 3; Eap, extracellular adherence protein; Efb, extracellular fibrinogen-binding protein; FcγRIIa, low-affinity immunoglobulin gamma Fc region receptor II-a; gC1Qr, receptor for the globular heads of C1q; Ig, immunoglobulin; LPS, lipopolysaccharide; LTA, lipoteichoic acid; PAF(R), platelet-activating factor (receptor); PAR, platelet-activating factor; PLC, phospholipase C; Rgp, recombinant gingipain; ROS, reactive oxygen species; SSL, staphylococcal superantigen-like; TLR, toll-like receptor; vWF, von Willebrand factor.
bacterial attachment to the platelet.\textsuperscript{10} Ultimately, engagement of receptors by bacteria and their products leads to common and species-specific intracellular signaling events in platelets.\textsuperscript{83}

Table 2 summarizes platelet receptors that mediate binding of bacteria to cause platelet activation and aggregation. A key mechanism for bacterial adhesion to platelets, which is described for various bacteria, involves αlβ3 integrin activation, the FcγRIIa receptor, and IgG,\textsuperscript{84} where platelet factor (PF)-4 may potentiate further binding of additional bacteria by forming an immunocomplex with bacteria that bind through FcγRIIa.\textsuperscript{85}

Platelets also express C–C motif and C–X–C motif chemokine receptors such as CCR1, CCR2, CCR4, and CXCR4,\textsuperscript{86} which can detect all four classes of chemokines (C, CC, CXC, and CXC). These receptors allow platelets to recognize and prioritize chemotactic signals and result in rapid vectoring of platelets to sites of infection.\textsuperscript{9} They are also involved in stimulating platelet adhesion, aggregation, and secretion.\textsuperscript{87} Additionally, platelet activation leads to activation of the complement system,\textsuperscript{88,89} and platelets also express various complement receptors after activation such as CR2, CR3, CR4, C3aR, C5aR, C1r$\gamma$M, and gC1qR.\textsuperscript{3} These may therefore serve as potential receptors for bacteria coated with complement factors, and lead to platelet aggregation.\textsuperscript{11} Furthermore, an important class of receptors for pathogen sensing are TLRs, and platelets express numerous TLRs to detect the molecular features of microbes.\textsuperscript{21,90–92} Platelets express, among others, functional TLR4,\textsuperscript{93} as well as the accessory component for LPS signaling, including CD14, MD2, and myeloid differentiation primary response (MyD)-88.\textsuperscript{94}

### Bacterial Products Affect Platelet Functions

Platelets are able to respond to many bacterial products, and these products modulate platelet function.\textsuperscript{25} LPS can stimulate platelet secretion of dense and α-granules through TLR4/MyD88 and cyclic guanosine monophosphate (cGMP)/cGMP-dependent protein kinase (PKG) signaling pathways.\textsuperscript{94} This potentiates secretion-dependent integrin activation and platelet aggregation. Further to this, platelets recognize and discriminate between various isoforms of bacterial LPS and secrete differential cytokine profiles against these danger signals.\textsuperscript{95,96} LPS also induces sCD40L release from platelets,\textsuperscript{97} as well as ROS generation.\textsuperscript{98} Some sources of LPS can activate TLR2,\textsuperscript{99–101} and this has also been implicated in LPS-induced cGMP elevation and platelet activation.\textsuperscript{94} However, LPS is described as not always generating conventional platelet activation (e.g., typical P-selectin release from α-granules).\textsuperscript{25} Bacterial structures from gram-positive bacteria such as lipoteichoic acid, peptidoglycan, and LTA are TLR2 ligands, and also trigger platelet activation.\textsuperscript{92,102} TLR activation in platelets induces a thromboinflammatory response, including platelet aggregation, formation of platelet–leukocyte complexes, and ROS generation\textsuperscript{103} as well as the elaboration of acute-phase reactants like TNF-α.\textsuperscript{91} However, studies have shown mixed effects of TLR2 agonists and LTA on platelet aggregation.\textsuperscript{104,105}

Platelets can migrate toward the chemotactic signal of bacterial N-formyl peptide by their receptors for this peptide.\textsuperscript{106} The gingipain proteases HRgpA and RgpB from *P. gingivalis* activate platelet protease-activated receptor (PAR)-1 and PAR4, leading to platelet aggregation.\textsuperscript{107,108} S. aureus α-toxin also causes platelet activation and leads to

Abbreviations: CfI, clumping factor; FnBPA, fibronec tin-binding protein A; IsdB, iron-regulated surface determinant B; PadA, platelet adherence protein A; PavB, pneumococcal adherence and virulence factor B; PspC, pneumococcal surface protein C; Sdr, serine-aspartate repeat protein; SpA, staphylococcal protein A; SrpA, serine-rich protein A; Ssp, stringent starvation protein; vWF, von Willebrand factor.
enhanced prothrombinase activity on the platelet surface.\textsuperscript{109,110} Staphylococcal superantigen-like (SSL)-5 from \textit{S. aureus} additionally induces platelet activation via platelet receptors GpVI and GpIIb,\textsuperscript{111,112} whereas the Panton–Valentine leukocidin toxin leads to platelet activation via neutrophil secretion products from damaged neutrophils.\textsuperscript{113}

Another class of exotoxins from \textit{S. aureus}, extracellular adherence protein (Eap) and extracellular fibrinogen-binding protein (Efb) fibrinogen-binding proteins, also interacts with platelets. On the one hand, Eap enhances αIIbβ3 integrin activation, granule secretion, and aggregation,\textsuperscript{114} whereas Efb inhibits platelet activation and aggregation\textsuperscript{115,116} and has powerful antplatelet actions.\textsuperscript{117} \textit{Staphylococcus aureus} enterotoxin B similarly inhibits platelet aggregation.\textsuperscript{118} LTA from \textit{S. aureus} has also been reported to inhibit platelet activation through platelet-activating factor (PAF) receptor and raised cyclic adenosine monophosphate (cAMP),\textsuperscript{119} as well as to inhibit platelet aggregation,\textsuperscript{120–122} but may support platelet adhesion to \textit{Staphylococcus epidermidis}.\textsuperscript{123} Additional products released by \textit{S. aureus} also have opposing functions on platelet aggregation. While staphylotherombin mediates fibrin formation that supports aggregation,\textsuperscript{124} staphylokinase prevents aggregation by degrading fibrinogen.\textsuperscript{125}

Bacterial toxins can also cause platelet destruction. For example, α-toxin from \textit{S. aureus} and α-hemolysin from \textit{E. coli}\textsuperscript{126} as well as peptidoglycan from \textit{S. aureus}\textsuperscript{127} can induce platelet apoptosis. Indeed, these pore-toxins stimulate disturbances in the platelet membrane and can be cytotoxic.\textsuperscript{3,128} \textit{Escherichia coli} Shiga toxin causes downregulation of platelet CD47 expression, which leads to enhanced platelet activation and phagocytosis of platelets by macrophages.\textsuperscript{129} Toxins such as pneumolysin from \textit{Streptococcus pneumoniae}\textsuperscript{130} and α-toxin from \textit{S. aureus}\textsuperscript{131} can cause platelet lysis, whereas streptolysin O from \textit{Streptococcus pyogenes}\textsuperscript{132} and phospholipase C from \textit{Clostridium perfringens}\textsuperscript{133} induce the formation of platelet–leukocyte complexes.

**Platelets Mediate Antimicrobial Attack**

A further function of platelets in bacterial infection is mediating antimicrobial attack. Platelets mediate some of their antimicrobial actions through the secretion of antimicrobial proteins from their α-granules.\textsuperscript{8,35} Moreover, platelets rapidly form clusters around bacteria that have been captured by Kupffer cells in the liver sinusoids (specialized macrophages in the liver), encasing the bacterium and facilitating its destruction.\textsuperscript{13} Further, sCD40L causes increased generation and release of reactive oxygen (e.g., superoxide) and nitrogen (e.g., nitric oxide) species by platelets, which assists in pathogen destruction.\textsuperscript{134,135}

Platelets are able to bind to and endocytose/phagocytose bacteria through engulfing endosome-like vacuoles that are formed by membrane endocytosis and become the site of α-granule release for the granular proteins to access the pathogen.\textsuperscript{136,137} A mechanism of internalizing bacteria via the open canalicular system has also been proposed\textsuperscript{138} (compare with Boukour and Cramer\textsuperscript{139}). Nonetheless, the platelet FcγRIIa receptor can bind IgG complexes and allows platelets to clear these complexes from the circulation.\textsuperscript{140} Internalization of IgG-coated particles results in platelet activation and the release of RANTES and sCD40L.\textsuperscript{141} Platelets opsonized by IgG can be destroyed by Fc-mediated platelet phagocytosis, contributing to the clearance of IgG-containing complexes from the circulation.\textsuperscript{142,143} More broadly, activated platelets expose phosphatidylserine, and neutrophils have been shown to phagocytose activated platelets in a clearance program involving phosphatidylserine and P-selectin.\textsuperscript{144–146}

**Platelet Interactions with Viruses**

Viruses have been observed to interact directly with platelets. Various viruses have been identified adsorbed to or inside platelets, including influenza virus,\textsuperscript{147,148} HIV,\textsuperscript{136,149,150} hepatitis C,\textsuperscript{151–153} and herpes simplex virus\textsuperscript{154} as well as others such as vaccinia virus\textsuperscript{155} and dengue virus.\textsuperscript{156–158} However, the interactions between viruses and platelets are less well characterized compared with those of gram-positive bacteria. This section describes the interaction of platelets with viruses, which are summarized in – Fig. 6.

**Platelet Receptors in Viral Pathogen Sensing**

Several platelet receptors have been identified to mediate binding to viral particles,\textsuperscript{6,7,30,159} and are summarized in – Table 3. Similarly to bacteria, IgG is important for the adhesion of viral particles to platelets, where IgG-coated particles can interact with the FcγRIIa receptor\textsuperscript{151,160–162} to be internalized into the platelet.\textsuperscript{140} However, other antibody-dependent mechanisms that enhance viral binding to platelets are also described,\textsuperscript{156} and platelets can further bind viruses in a receptor-independent manner.\textsuperscript{163} For example, although the coxsackievirus and adenovirus receptor (CAR) is expressed on platelets, coxsackie B virus interaction with platelets has also been described independently of CAR and can result in P-selectin and phosphatidylserine exposure.\textsuperscript{163} More broadly, β3 integrins are important platelet-adhesion receptors, and these receptors appear to facilitate viral adhesion to platelets.\textsuperscript{165,166} Even though various receptors that are expressed on platelets have been implicated in viral adhesion and cell entry, the direct effect of this interaction on the platelet has not always been described.

Platelets can also detect viruses through TLRs. Platelet TLR2 can bind cytomegalovirus, which triggers platelet activation, degranulation, and the formation of platelet-leukocyte aggregates.\textsuperscript{165} TLR7 recognizes the classical viral PAMP, single-stranded RNA.\textsuperscript{92} Platelets express functional TLR7, and activation via TLR7 leads to expression of CD40L and P-selectin, and P-selectin supports the adhesion of virally activated platelets to neutrophils.\textsuperscript{22,166} Moreover, platelet TLR7 mediates complement C3 release from platelets, which in turn leads to platelet–neutrophil aggregation and NET release by neutrophils.\textsuperscript{167} Encephalomyocarditis virus has been shown to interact with platelet TLR7.\textsuperscript{166} Platelet TLR9 recognizes unmethylated CpG islands found in bacterial and viral DNA, which also leads to P-selectin surface expression.\textsuperscript{92,168}
Viral Products Affect Platelet Functions

Viruses secrete various products that modulate platelet function. The secreted HIV Tat protein directly interacts with platelets in a process requiring the platelet receptors CCR3 and β3 integrin as well as calcium influx. This leads to platelet activation and CD40L expression as well as microparticle formation. Indeed, platelet activation persists even in virologically suppressed HIV infection. Viral enzymes such as neuraminidase can cause desialylation of platelet surface receptors, and desialylation might promote platelet clearance in the liver.

Platelets Mediate Antiviral Attack

The secretory products of platelets can also exert virucidal effects, including the inactivation of adenovirus, poliovirus and vaccinia virus, and HIV suppression. Moreover, platelets exhibit phagocytic behavior toward viruses such as HIV and can form engulfing vacuoles that lead to granular components being secreted on the virus particle, as described for bacteria. Indeed, intact HIV-1 particles enclosed in endocytic vesicles have been found in the open canalicular system. Recently, it has been proposed that platelets may also potentially phagocytose influenza virus. Platelets may then...
cause disruption of viral integrity.\textsuperscript{174} Overall, it has been suggested that internalization of viral particles by platelets may function to clear viruses from the circulation.\textsuperscript{177}

Viruses can cause the expression of P-selectin and phosphatidylinerine exposure on platelets, and these components promote interactions with leukocytes as well as lead to phagocytosis of the platelet.\textsuperscript{163,178} Interaction between platelets and viruses can also lead to sequestration to the reticuloendothelial system of the liver, where virus–platelet aggregates can be taken up by Kupffer cells and degraded.\textsuperscript{179} Spleen macrophages also assist in clearing platelets with a viral load.\textsuperscript{30}

### Conclusion

Platelets are among the first cells to accumulate at sites of infection and inflammation, and can be considered as first responders to invading pathogens. Here, platelets have a key role in sensing and effecting the first wave of responses to microbial and viral threat.\textsuperscript{8,9} This is achieved by the inflammatory activity of platelets but also through direct antibacterial and antiviral actions that facilitate the clearance of pathogens from the circulation. Platelets are therefore represented at the interface of hemostasis, inflammation, and antimicrobial host defense. Their position at the crossroads of these processes emphasizes their role as signaling entities in infection and inflammation.

Various stimuli that are relevant to infection impinge on platelets, activating and forcing them to exert their effector actions. Recursive stimulation of activation receptors and successive activation of bystander platelets intensify the host-defense functions of platelets even at threshold stoichiometric ratios of platelets to pathogens.\textsuperscript{180} Platelets face inappropriate activation and immunological destruction, and are inevitably consumed by their participation in host defense. An inflammatory milieu can thereby drive platelet dysfunction. In this review, we emphasize that platelet dysfunction can arise as a general consequence of an exaggerated systemic (immune) response to infection. Increased platelet consumption and removal can lead to thrombocytopenia, which is frequently observed during infection. \textsuperscript{181} Fig. 7 summarizes and links together the various processes we have discussed, to show a general mechanism of platelet depletion during infection.

Because of their largely protective role, lower platelet counts are associated with worse prognosis and greater likelihood of infection; however, platelets are also presented as having an ambivalent role in infections by possibly sheltering pathogens in certain cases.\textsuperscript{6,7,9,12,30,181} Nonetheless, in the context of impairment of the immune system, the functions of platelets become more important. Following the contribution of platelets to diverse immunological processes, dysregulation of platelet–leukocyte interactions, which are important for inflammatory and immune reactions, together with dysregulation of inflammatory mediators, establish an excessive and unbalanced systemic inflammatory response. In this context, platelets can contribute to pathophysiological processes and immunopathology, and become dysfunctional.

Achieving a balance between pro- and anti-inflammatory responses during infection is difficult to manipulate.
effectively in a therapeutic context. Following from the diverse functions of platelets in infections, platelets are also placed at an interface between health and disease. Platelets are acutely affected by the surrounding environment. This, together with other characteristics of platelets such as their fast turnover, might position platelets as relevant signaling entities with clinical potential in disease tracking and targeting to evaluate or manage the course of infections. Although platelets are perhaps a lesser-known participant in the host-defense system, their large-scale depletion may cause significant health issues. Managing a generic depletion of platelets during the presence of infection should possibly be a more actively pursued clinical goal. The key points encapsulating the main ideas of this review are presented in Table 4.

**Table 4 Key points**

- Platelets are versatile cells positioned at the interface of hemostasis, inflammation, and antimicrobial host defense, and their immune, antibacterial, and antiviral actions establish them as active participants in infection.
- By nature of their normal functioning, platelets are invariably and irreversibly expended in the processes to which they contribute.
- During infection, an onslaught of inflammatory and pathogen-derived stimuli can evoke and challenge platelets, leading to inappropriate activation, immunological destruction, and sequestration.
- In the context of a dysregulated host response to infection, platelets can experience overwhelming activation and, consequently, consumption, and this represents a generic large-scale mechanism for platelet depletion in infection.
Author Contribution Statement
M.P.: wrote paper, prepared figures; E.P.: wrote parts of the paper, study leader, and corresponding author. Both authors edited and reviewed the manuscript.

Conflicts of Interest
The authors have no competing interests to declare. Mr. Page is supported by the Skye Foundation and the Harry Crossley Foundation. Dr. Pretorius reports grants from the Medical Research Council of South Africa.

Acknowledgments
We thank the Medical Research Council of South Africa (Self-Initiated Research Program) for supporting our research. The funders had no role in the design and preparation of the manuscript or decision to publish.
