Cardiovascular Comorbidities in Women with Psoriasis

Durga Prasad Annabathula¹

¹Department of Dermatology, DERMACARE, Hyderabad, India

The prevalence of cardiovascular (CV) risk factors among psoriasis patients is well-known, and therefore there is an elevated risk of CV disease (CVD). Psoriasis is associated with an elevated risk of myocardial infarction, stroke, and also death caused by CVD, which are as a whole referred to as major adverse cardiovascular events (MACE). It also has been detailed that the magnitude of these risk factors is directly proportionate to the severity of psoriasis.

Atherosclerosis, which is a chronic inflammatory disease of the blood vessels, is usually the cause for CVD. Atherosclerosis is associated with both innate and adaptive immune responses that involve the Th-1 and Th-17 pathways. On the other hand, psoriasis is also a chronic inflammatory disorder which displays its association with Th-1 and Th-17 mediated inflammation, resulting in production of IL-17, INF-gamma and TNF and leading to the formation of plaques over the skin. This similarity in the immunological and inflammatory pathways implies a relationship between CVD and psoriasis.

The various determinants of CVD evaluated in this study were elevated waist circumference (> 80 cm), raised triglycerides (> 150 mg/dL), reduced high-density lipoprotein (HDL) (< 50), fasting blood glucose (> 100 mg/dL), and raised blood pressure which constitute the metabolic syndrome, especially in women. Also, inflammation increases the degree of occurrence of metabolic syndrome, particularly in women, which, in turn, elevates the CV risk. Given that psoriasis is a chronic inflammatory disease, it poses a greater risk of CVD in women. This study showed higher prevalence of metabolic syndrome in cases with psoriasis than in controls, which is in accordance with the research conducted by Regitz-Zagrosek et al.

It has been concluded in a study done by Pietrzak et al. that the relation of CVD and psoriasis in females intensifies with age. However, no such associations have been recorded in this study.

It is demonstrated by this study that hsCRP, which is an important indicator of atherosclerosis, was raised in patients with psoriasis, in close agreement with the study carried out by Jindal et al. It was also stated by this study that CIMT, which is a salient tool for the measurement of subclinical atherosclerotic changes, was elevated among psoriasis cases than in controls which is, again, in conformity with Jindal et al.

All the other determinants of CVD evaluated in this study had higher incidence in women with psoriasis than in women without psoriasis, which is in correspondence with Jindal et al.

Therefore, it is of utmost importance that the female patients with psoriasis be orderly screened for the various CV risk factors for early detection and prevention of CVD.

Conflict of Interest
None declared.
