1Department of Pediatric Surgery, Institute of Medical Sciences, Banaras Hindu University, Varanasi, Uttar Pradesh, India

Introduction
To study the clinical features, diagnosis and treatment of mesenteric cysts in pediatric age group (< 15 years).

Materials and Methods
This was a retrospective analysis which inculded 35 children diagnosed and treated for mesenteric cysts in the pediatric surgery department from January 2014 to January 2019. Patient’s data were retrieved from case sheets and analyzed. Patients with atleast one year follow-up were included in the study.

Results
Thirty-five patients were included in the study. Twenty-one (60%) were males and fourteen (40%) were females. Mean age of presentation and surgery was 24 months. Twenty-six (74.2%) patients were managed by bowel resection, while 9 (25.7%) were managed by simple cystectomy. The average size of the cyst was 15 cm (ranging from 5 to 25 cm). Content of cysts was mostly chylous (82.9% cases). No recurrence was found throughout the follow-up period (1–2 years).

Conclusion
Mesenteric cyst should be considered as a differential diagnosis in pediatric patients with acute or subacute intestinal obstruction and with or without a palpable lump in the abdomen. Mesenteric cysts can be managed surgically with favorable outcomes.

Abstract
Introduction To study the clinical features, diagnosis and treatment of mesenteric cysts in pediatric age group (< 15 years).

Conclusion Mesenteric cyst should be considered as a differential diagnosis in pediatric patients with acute or subacute intestinal obstruction and with or without a palpable lump in the abdomen. Mesenteric cysts can be managed surgically with favorable outcomes.

Introduction
Mesenteric cyst is a rare abdominal tumor. Incidence of this lesion in the pediatric age group has been reported as 1 in 20,000 admissions.1 They lack characteristic clinical features and radiological signs and thus encounter great diagnostic difficulties. The cyst may present as nonspecific abdominal features, acute abdomen, or an incidental finding. Abdominal pain is the major presenting symptom. Abdominal mass was reported to be present in more than 50% of cases and 40% of cases were discovered incidentally.1,2 Mesenteric cysts have been reported from the duodenum to the rectum and most of them are located in ileal mesentery.3–6

Objectives
To study the clinical features, diagnosis, complications, and treatment of mesenteric cysts in the pediatric age group (< 15 years).

Materials and Methods
This study represents a retrospective analysis of 35 children diagnosed and treated for mesenteric cysts in the pediatric surgery department from January 2014 to January 2019. Patient’s data were retrieved from case sheets and analyzed. Patients with atleast 1-year follow-up were included in the study. Ultrasonography and CT scan of abdomen were done for imaging purposes. Patients with atleast 1-year follow-up were included in the study. Patients of age more than 15 years and lost to follow-up were excluded. Clinical, radiological, peroperative, and histopathological findings were analyzed.

Results
Out of 35 patients, 21 (60%) were boys and 14 (40%) were girls, with male to female ratio of 1.5:1. The mean age at presentation was 24 months affecting newborns to twelve years of age. Twenty-two (62.8%) patients presented with

subacute intestinal obstruction, 9 (25.7%) patients with a palpable abdominal mass, and the rest (4–11.4%) were diagnosed intraoperatively when laparotomy was done for other acute abdominal conditions. Ultrasonography was done in 31 (88.5%) cases, while CT scan of abdomen was done in 23 (65.7%) patients (►Table 1). Most of the mesenteric cysts were ileal mesentery 27 (77.1%) (►Fig. 1), followed by five (14.3%) cases in jejunal mesentery, 2 omental cysts (►Fig. 2), and 1 colonic cyst (►Fig. 3). Twenty-six (74.2%) patients were managed by bowel resection, while 9 (25.7%) were managed by simple cystectomy. Twenty-one (60%) cases of cyst were multiloculated, while 14 (40%) cases were uniloculated. Mean size of cysts was 15 cm (range from 5 to 25 cm) in largest diameter. Content of cysts was mostly chylous (82.9% cases), serous in 2 cases, and mixed in 4 cases (►Table 2). Histopathology showed lining of the cyst wall varied from flattened endothelial layer to a cuboidal/columnar layer and no malignant transformations were seen. Three patients developed adhesive ileus within 3 months of follow-up in the postoperative period which were managed conservatively. Recurrence was not noted in follow-up of 2 years.

Discussion

Mesenteric cyst is defined as any cyst which arises from mesentery along the gastrointestinal tract from duodenum up to the rectum. The mesenteric cyst is a rare presentation and incidence is 1 in 105000 admissions to general hospital and 1 in 200000 admissions to pediatric hospital. One third of mesenteric cysts occur in children less than 10 years of age.3–7

The mesenteric cyst was first reported by anatomist Benevien in 1507. In 1842, Von Rokitansky was the first to describe a chylous mesenteric cyst. In 1880, French surgeon Tillaux carried out the first successful surgery. In 1883, the first marsupialization was done by Pean.8

The exact etiology of mesenteric cysts is not known. Various theories have been proposed such as failure of leaves of the mesentery to fuse, occult trauma, neoplasia, localized degeneration of lymph node, and obstruction and/or degeneration of exiting lymphatic channels.9

Published literatures describe the most common location of mesenteric cyst is small bowel mesentery. Ileal (60%) was

![Fig. 1](image1.jpg) A 5-year-old male patient with obstruction, ileal mesenteric cyst was found on laparotomy, resection of cyst with ileal segment and ileoileal anastomosis was done.

![Fig. 2](image2.jpg) Ultrasoundography of a 3-year-old female with abdominal lump showing multiseptated large cyst, omental cyst was found on laparotomy, cystectomy with omentectomy was done.

![Fig. 3](image3.jpg) CT scan abdomen of a 6-month-old male patient with left ileac fossa mass showing colonic cyst; laparotomy with excision of cyst was done.
the most common type, followed by mesocolon (24%–most common sigmoid mesocolon), retroperitoneum (15%), and isolated omental cysts (< 1%).10 Mesenteric cyst can be single or multiple, unilocular or multilocular, and filled with content that can be serous (distal small bowel/colonic mesentery), chylous (proximal small bowel), hemorrhagic, or mixed.11,12 The lining of cyst can varied from flattened endothelial layer to a cuboidal or columnar layer.13 Similar findings were also observed in the study.

The classical presentation may varied from subacute intestinal obstruction combined with freely movable abdominal mass to acute abdomen.3,6 The most common mode of presentation in children was small bowel obstruction, which were associated with volvulus and intestinal perforation.3,6,11

Ultrasonography (USG) of the abdomen have been preferred by many surgeons as investigation of choice.2,6 CT scan remains gold standard investigation as per many research papers for better anatomical orientation and identification of the adjacent organs.2,14 Although USG and/or CT scan of the abdomen is helpful in making the preoperative diagnosis of mesenteric cysts in a majority of the cases, it is not always possible and diagnosis is confirmed during surgical exploration many a times.3,15

Management using surgical approach can involve simple drainage, resection either by laparotomy or minimal invasive approach. As a rule, drainage is not recommended because the cyst tends to reaccumulate, and marsupialization is not acceptable, because of the risk of infection and/or reoperation for persistently draining sinus.16 Full excision of the cyst with or without its mesenteric origin should be the aim of surgery, because recurrence is uncommon following total resection. Localized resection of the intestine with cyst does not significantly alter morbidity.17 Minimal access techniques have been widely introduced in surgical practice. Laparoscopy provides visualization of the peritoneal cavity and retroperitoneal space and should prove to be the diagnostic procedure of choice in cases that remain unclear. Accurate anatomical, structural, and pathological assessment of the cyst can be made rapidly. In 1993, successful laparoscopic excision of mesenteric cysts was described by Mckenzie.18 Laparoscopic surgery made it possible to remove cysts without complications in select cases; the postoperative period can be more comfortable. However, in cases where cysts cannot be completely excised, the requirement of the second operation and incomplete excision in retroperitoneal cases are disadvantages of laparoscopic surgery.18-20

In our study, there were no deaths, and no patient complained of recurrence in follow-up. Prognosis following complete surgical excision of the mesenteric cyst is excellent, although recurrence has been reported and is more in the cases where the complete excision of the mesenteric cysts was not possible.1-5

### Conclusion
Mesenteric cysts should be considered as a differential diagnosis in pediatric patients with acute abdomen and with or without a palpable lump in the abdomen. Mesenteric cysts are managed surgically (excision of cyst along with adjacent bowel usually) with favorable outcomes either with open or laparoscopy; recurrence not reported with complete excision of the cyst.
