Intradural Spinal Arachnoid Cyst in a Pediatric Patient: A Case Report

Cisto aracnoide espinhal intradural em paciente pediátrico: um relato de caso

Abstract

The present case reports a 13-year-old patient with an intradural arachnoid cyst, which manifested itself with a sudden loss of strength and sensitivity in the lower and upper limbs and a severe pain in the cervical and thoracic region. On examination, a lesion displayed as an intradural hematoma; however, a laminotomy was performed and it was realized that the lesion was an arachnoid spinal cyst of the cervical-dorsal spine.

Resumo

O presente trabalho relata o caso de um paciente de 13 anos que apresentou um cisto aracnoide intradural espinhal, que se manifestou com uma perda súbita de força e sensibilidade nos membros inferiores e superiores, bem como uma forte dor nas regiões cervical e torácica. Ao exame, a lesão apresentou-se como um hematoma intradural; todavia, ao ser realizada a laminectomia, tratava-se de um cisto aracnoide espinhal da coluna vertebral cérvico-dorsal à direita.

Introduction

Spinal arachnoid cysts are uncommon, and intradural cysts are even less common, although the pediatric population is more likely to have an intradural cyst compared with the general population.1-3 The intradural cyst consists of an arachnoid bag filled with cerebrospinal fluid, which consists in a benign lesion that is entirely in the dural space.4,5 The course of the spinal arachnoid cyst is not fully understood, and many authors create theories to explain the pathophysiology.3

During the first two decades of the patient’s life, age and gender do not play an important role in the incidence of the cyst. However, most of the reported cases are single cysts and occur commonly at the level of the thoracic spinal cord, located more often dorsally to the neural elements.

Case Report

A 13-year-old male patient arrived at the emergency care unit complaining of sudden back pain in the cervical and thoracic region. At nightfall on the same day, the patient developed severe pain and progressive loss of strength in the legs, resulting in difficulty in walking, followed by loss of sensation, initially in the right lower limb and then in the left lower limb. He was medicated with intravenous symptomatic drugs, however he continued without any improvement in pain. After the patient was forwarded to the hospital, the computed tomography (CT) scan of the cervical and thoracic spine suggested that he had an injury at the C5-C6 level, with a slightly increased density in the vertebral canal. On physical examination, he had hemiplegia in his right lower limb and weak movement in his left lower limb, with an asymmetric degree of strength (worse on the right). He also had a tingling sensation and decreased bilateral tactile and thermoalgesic sensitivity down to the level of the nipples, strength grade 3 on the right upper limb and grade 2 on the left upper limb. Trauma, as well as similar episodes and symptoms, were denied previously. The patient did not use continuous medications, had never undergone surgery or previous hospitalizations. After performing cervical and dorsal spine magnetic resonance imaging (MRI) with weighted sequences in T1 and T2 in the axial and sagittal planes, an expansive lesion was observed in the right posterolateral portion of the spinal canal in an epidural situation, in the C6, C7 and D1 segment, measuring $3.2 \times 1.3$ cm (largest craniocaudal diameter), hyposignal in the T2-weighted sequence and slightly in hypersignal in T1, compatible with the diagnostic hypothesis of hematoma. This injury had a compressive effect, with alteration in the signal intensity of the adjacent spinal cord (edema). The laminotomy procedure of the C7-D2 segment was performed, and when entering the arachnoid membrane there

![Fig. 1](image1.png)  
**Fig. 1** Sagittal T2 section shows a lesion in high signal intensity at the right posterolateral level of C6 to D1.

was a large spillage of cerebrospinal fluid under high pressure. It was observed that the lesions consisted of a cystic intradural arachnoid lesion and the resection was performed. The anatomopathological result indicated a tiny fragment of connective tissue, apparently derived from the arachnoid, in continuity with some red blood cells. In the postsurgical period, the patient continually improved the pain, the strength and the sensitivity.

Discussion

Arachnoid cysts are often attributed to congenital defects, therefore being etiology as the main origin by the authors.\(^1\),\(^5\),\(^9\) Although their etiology is inconsistent, it is believed that some of these cysts are derived from trauma, hemorrhage, anesthetic procedures and secondary to inflammation, such as meningitis and arachnoiditis.\(^10\) Despite these cysts being frequently asymptomatic, they eventually are able to produce symptoms when they compress the spinal cord and/or nerve roots, both suddenly and in a progressive manner.\(^8\) They are able to cause pain, weakness, sensory changes, and gait disorders.\(^1\),\(^1\) Large cysts located in the lumbar spine can also lead to loss of bladder and/or intestine control and cramps.\(^4\)

In cases of symptomatic injuries, surgical treatment must occur and is usually performed by simple fenestration or limited laminotomy. The purpose of surgery is neural decompression and prevention of cyst replenishment. Therefore, the cyst is completely dried out and the communication with the arachnoid space is closed, repairing the dural failure.\(^1\)–\(^1\) If left untreated, spinal cysts would cause permanent severe neurological damage. In the case of asymptomatic individuals, is indicated the constant monitoring of the cyst.

Neurological deficits from arachnoid cysts are treatable. Surgical intervention shows excellent postoperative results. Most patients present complete or significant recovery, and many remain stable, even when symptoms have been present for a long time.\(^1\),\(^1\)\(^4\),\(^1\)

About the negative findings from this pathology, the most invasive opening in repeated laminectomies is related to complications such as kyphoscoliosis.\(^2\) The patient may also develop syringomyelia and slow progressive myelopathy.\(^5\),\(^8\),\(^1\)

Conclusion

Arachnoid cysts of the spine are lesions of uncertain etiology and may not have the characteristics of a cerebrospinal fluid sign on MRI and simulate other pathologies. What is clearly known is that cysts that cause compression of the spinal cord and surrounding nerves cause significant neurological deficits in the patient. Therefore, it is essential to perform a surgical procedure as soon as possible to obtain the best possible result for the condition, which is complete neurological recovery.
