Abstract

High on-treatment platelet reactivity (HPR) with P2Y₁₂ receptor antagonists in patients treated with dual antiplatelet therapy (DAPT) is strongly associated with adverse ischemic events after percutaneous coronary intervention (PCI). This prospective study was conducted to assess individual platelet response and HPR to antiplatelet medications in post-PCI cases by thromboelastography platelet mapping (TEG-PM). Total 82 patients who were on aspirin and on either clopidogrel, prasugrel, or ticagrelor were evaluated. The percentage of platelet inhibition to arachidonic acid (AA) and adenosine diphosphate (ADP) was calculated by \[100 - \frac{(MA_{ADP}/AA - MA_{Fibrin})}{(MA_{Thrombin} - MA_{Fibrin})} \times 100\], taking 50% response as cut-off for HPR. HPR to clopidogrel and prasugrel was 14.29 and 12.5%, respectively. No HPR was detected to aspirin and ticagrelor. The mean percentage of platelet inhibition was significantly higher in patients with ticagrelor 82.99, 95% confidence interval (CI) of [77.3, 88.7] as compared with clopidogrel 72.21, 95% CI of [65.3, 79.1] and prasugrel 64.2, 95% CI of [52.5, 75.9] (p-value of 0.041 and 0.003, respectively). Aspirin along with ticagrelor is associated with a higher mean percentage of platelet inhibition, and lower HPR as compared with the usage of aspirin combined with clopidogrel or prasugrel. Additionally, it might also be concluded that TEG-PM could be used effectively to measure the individual platelet functions which would make oral antiplatelet therapy more personalized for cardiac patients.

Journal of Cardiac Critical Care

Materials and Methods

Study Details

This was a prospective, observational, single-center cohort study where TEG-PM was performed in a group of patients to assess the platelet functions after starting DAPT. All these patients underwent PCI due to coronary artery disease (CAD) from June 2016 to December 2018 at a cardiac center in Eastern India. Institutional review board (ECR/587/Inst/WB/2014/RR-17) approval was obtained for this study. Informed consent was taken from each patient before PCI.

Study Population and Design

Inclusion criteria for this study were patients aged more than 18 years, had confirmed CAD, and underwent PCI. All patients considered for the study were on aspirin and on either clopidogrel, prasugrel, or ticagrelor in combination. The exclusion criteria were known cases of bleeding diathesis, had a history of drug allergy against any of the antiplatelet drug, a platelet count less than $10^9/L$, or greater than $500 \times 10^9/L$, history of active bleeding within the previous 3 months, any other major surgical procedure within 2 weeks prior to the PCI, known case of active liver disease, prothrombin time $>1.5$ times of control, hematocrit $<30\%$, creatinine $>0.354$ mmol/L, any recent use of nonsteroidal anti-inflammatory drugs (NSAIDs), or glycoprotein (GP) IIb/IIIa inhibitors. During the study period, 105 patients initially met the inclusion criteria. Among 105 patients, 23 were excluded from this study because they had gastrointestinal reflux after starting of DAPT maintenance dose, leading to change of medications or premature stoppage of one antiplatelet drug or history of irregular drug intake. Finally, a total of 82 patients were tested by TEG-PM assay and data were collected prospectively. On the day of PCI procedure, a loading dose of 325-mg aspirin was administered in each patient along with a loading dose of either 300-mg clopidogrel, 60-mg prasugrel, or 180-mg ticagrelor. Maintenance dose of P2Y12 receptor antagonist (clopidogrel, 75-mg once per day; prasugrel, 10-mg once per day; or ticagrelor, 90-mg twice daily) was started after 24 hours of procedure along with maintenance dose of aspirin (75–100 mg once per day). The response to the treatment was assessed in each patient by TEG-PM after 1 week of starting DAPT. Patients with HPR to a specific P2Y12 receptor antagonist were switched over to another combination of DAPT and followed-up clinically.

Pharmacology of P2Y12 Receptor Antagonists

Clopidogrel and prasugrel are thienopyridine prodrugs that transformed into active metabolites by hepatic CYP enzymes. Those active metabolites bind to the platelets, P2Y12 receptors are irreversible and produce inhibition of platelet function for the lifetime of the affected platelet. Most of the clopidogrel is hydrolyzed by carboxylesterase-1, leaving only trace amount available for active metabolite formation, which occurs predominantly by CYP2C19. Prasugrel is dependent to a lesser extent on CYP2C19 metabolism to form its active metabolite. Ticagrelor is a directly acting cyclopenyltriazolopyrimidine class molecule which is a reversible, noncompetitive P2Y12 receptor antagonist and does not require metabolism by CYP2C19. Clopidogrel has a slow onset of action, whereas ticagrelor provides the fastest platelets inhibition.

Blood Sampling and Platelet Function Analysis

Blood samples were obtained from patients in a fasting state during their first follow-up visit at cardiology outpatient department (OPD) after 1 week of starting DAPT. Samples were collected into separate vacutainer blood collecting tubes (BD Vacutainer, Becton Dickinson, United States) containing 3.2% trisodium citrate or lithium heparin.
After discarding the first 2 to 3 mL of blood, the Vacutainer tubes were filled to capacity and gently inverted 3 to 5 times to ensure complete mixing of the anticoagulant. Blood samples were analyzed in the transfusion medicine laboratory by trained personnel within an hour of receiving the blood sample as per the manufacturer instructions. Both analyzer (series 5000) and the reagents were from Haemoscope Corporation (Niles, Illinois, United States). The following TEG parameters were studied: reaction time (R), time to initial fibrin formation up to 2 mm; K time (K), time to clot formation up to 20 mm; α angle (α), speed of clot formation; and maximum amplitude (MA), measurement of clot strength. The normal reference values of TEG parameters (as provided by the manufacturer) for kaolin-activated citrated samples were taken as R = 2 to 8 minutes, K = 1 minute to 3 minutes, α = 55 to 78 degrees, and MA = 51 to 69 mm. Heparin was used as an antiagulant to eliminate thrombin activity in the sample during assay. Reptilase and activated factor XIII (activator F) were used to generate a cross-linked fibrin clot to isolate the fibrin contribution in clot strength. For maximal clot strength (MA, Thrombin) 1 mm of citrate stabilized blood was transferred to a vial containing kaolin and mixed by gentle inversion. Kaolin activated blood (340 μL) was added to a TEG cup containing 20 μL of 0.2 M CaCl₂. As MA, which is representing the maximal clot strength, can be ascertained by the binding of activated platelets to a fibrin mesh, 360 μL of heparinized blood was added to 10 μL of activator F (reptilase and factor XIIIa) and the contribution of each fibrin meshwork to clot strength (MA, Fibrin) was assessed. The contribution of P2Y₁₂ receptor or cyclooxygenase pathways to the clot formation can be measured by the addition of the appropriate agonist, ADP, or arachidonic acid (AA). Therefore, heparinized blood (360 μL) was added to a TEG cup in the presence of the activator F and agonist, 10 μL: ADP (2 μM, final concentration), yielding the (MA, ADP) or 10 μL: AA (1 μM, final concentration) for the MA, AA. The percentage of platelet inhibition to agonist was calculated by TEG-PM software as [100−{(MA, ADP,AA−MA, Fibrin) / (MA, Thrombin−MA, Fibrin) X 100}].

**Assessment of Outcome**

The percentage of HPR to clopidogrel, prasugrel, and ticagrelor was assessed and considered as the primary outcome of the study. The cut-off for HPR was set at 50% in response to each P2Y₁₂ receptor antagonist was also assessed during this study.

**Statistical Analysis**

Data were collected and analyzed by using Microsoft Excel statistics software package. Continuous variables were expressed as mean with standard deviation and categorical data were expressed as frequencies or percentages. Student’s t-test was applied for comparison of means and significance was established with p-values level of 0.05 (p < 0.05).

**Results**

All the demographic variables and baseline data were found similar in studied population (Table 1). The mean age of patients was 63.5 years (range: 44.5–73 years) and the mean weight was 58.3 kg (range: 47–81 kg). All patients were male. All 82 patients were treated with aspirin, 42 among them were treated with clopidogrel in combination, 16 with prasugrel, and 24 with ticagrelor in combination, respectively (Table 2). Fig. 1 is showing the number of HPR cases to each P2Y₁₂ receptor antagonist. Table 2 and Fig. 2 are showing that the mean percentage of platelet inhibition was significantly higher in patients with ticagrelor 82.99, 95% confidence interval (CI) of [77.3, 88.7] as compared with clopidogrel 72.21, 95% CI of [65.3, 79.1] and prasugrel 64.2, 95% CI of [52.5, 75.9] (p-value of 0.041 and 0.003, respectively). No bleeding manifestation was observed in any patient due to administration of DAPT.

**Abbreviation:** HPR: High on-treatment platelet reactivity.
Use of Thromboelastography Platelet Mapping

Datta et al.

Although HPR to prasugrel has not been well reported, it was found 12.5% in our study which is in agreement with the results of Bonello et al.\(^21\) where VASP method was used for assessment of platelet response. It was previously reported that ticagrelor has a mean percentage platelet inhibition of 80 to 90% when tested by platelets aggregometry\(^22\) which is again consistent with the current study finding of a mean percentage platelet inhibition of 82.99% with ticagrelor. Average percentage of platelet inhibition in patients treated with prasugrel (64.2%) was lower than clopidogrel (72.21%) in our study which is in agreement with the TRILOGY-ACS trial (targeted platelet inhibition to clarify the optimal strategy to medically manage acute coronary syndromes) where prasugrel was not found superior to clopidogrel in patients who had acute coronary syndromes (ACS).\(^23\) Although, meta-analysis\(^24\) of several studies showed a stronger antiplatelet effect of ticagrelor over prasugrel which is in favor of the present study; the recent ISAR-REACT 5 trial (intracoronary stenting and antithrombotic regimen 5)\(^25\) showed that a stronger antiplatelet effect is not always associated with better composite end results in ACS cases. There was no bleeding manifestation with ticagrelor therapy despite higher platelet inhibition which is similar to the results of the PLATO trial (platelet inhibition and patient outcomes)\(^26\). Also, no HPR to aspirin was found in our study which is in agreement with the results of Tantry et al.\(^27\) There were no ischemic complications observed after 6-month follow-up in patients with HPR who were switched over to another DAPT combination depending on TEG-PM results.

**Discussion**

Numerous studies have demonstrated substantial variability in platelet inhibition among patients treated with clopidogrel depending on the method of PFT and the definition of drug response.\(^12\) In our study, TEG-PM analysis was used to measure the HPR and it was found 14.29% to clopidogrel which is in agreement with other global studies on clopidogrel response where platelet response was evaluated either by optical light transmission platelets aggregometry or by flowcytometry.\(^15-16\) The P2Y\(_{12}\) receptor antagonist used in a post-PCI case is chosen based on the clinical assessment of risk for bleeding and cost of the therapy. Although, large randomized controlled trials like ARCTIC trial (the assessment of drug-eluting stent implantation and of treatment interruption vs. continuation of 1 year after stenting) or GRAVITAS trial (the gauging responsiveness with a VerifyNow assay—impact on thrombosis and safety) failed to demonstrate a sustainable clinical benefit of using a PFT-guided approach to antiplatelet therapy\(^7,18\) but the investigators of these studies have used PFT-guided dose escalation of clopidogrel rather than switch over to other DAPT combination. It is a well-known fact that in patients with CYP2C19 mutations, even maintenance doses as high as 300 mg daily of clopidogrel did not result in adequate platelet inhibition.\(^10\) No HPR to ticagrelor was found in our study which is almost similar to the results of Dalal et al.\(^20\)

**Limitations**

The major limitation of our study is the nonrandomized design. The sample size is small because of the poor affordability to this relatively costly test. Also, the follow-up test after switch over to a new DAPT combination was not possible due to the increase cost of the assay. Lack of gender distribution of results could be considered as another limitation as only male patients were evaluated. We did not have any provision to compare our test results with a more sensitive testing platforms like VerifyNow which has a defined HPR value for P2Y\(_{12}\) reaction assessment. Furthermore, the pharmacokinetic analysis of drug levels in blood was not performed in this study. Hence, precise correlation with the observed effects of the drugs is not possible.

**Conclusion**

Although, measurements of platelet reactivity can vary over time in a significant proportion of patients and treatment adjustment according to a single PFT at a single time point might not be sufficient for guiding antiplatelet therapy, but it is nearly impossible to use “gold-standard” technologies like CYP2C19 genotyping, platelets aggregometry, or flowcytometry routinely to monitor the effect of antiplatelet therapy in resource-limited health care facilities. Therefore, we conclude that aspirin along with ticagrelor is associated with a higher mean percentage of platelet inhibition and lower
HPR as compared with the usage of aspirin with clopidogrel or prasugrel. In addition to that, it might also be concluded that TEG-PM could be used effectively to measure the individual platelet functions in response to antiplatelet drugs and the decision of switching to another combination of DAPT in HPR cases could be taken based on this assessment. This treatment approach might be useful to make oral antiplatelet therapy more personalized for cardiac patients in developing countries.

**Ethics Approval**

Ethical approval was obtained from the Institution Ethics Committee of The Mission Hospital (ECR/587/Inst/WB/2014/RR-17) for this study.

**Consent**

Individual informed written consent was obtained from each patient before PCI.

**Data Transparency**

Raw data are available; data sheet can be shared on request.

**Authors’ Contributions**

S.S.D. and N.A.M. designed the study; S.S.D. performed the tests; collected data and prepared the draft. D.D. provided support during data analysis. S.S.D. prepared the manuscript. All authors reviewed the manuscript before submission.

**Funding**

We did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors for this study.

**Conflict of Interest**

The authors declare that they have no conflict of interest.

**Acknowledgment**

We are thankful to all the staffs of department of transfusion medicine for their support.
