Prevalence and Determinants of Adequate Compliance with Antenatal Care in Peru

Prevalência e determinantes da conformidade adequada à atenção pré-natal no Peru

Abstract

Objective To determine the adequacy of compliance with antenatal care (ANC) by pregnant women in Peru and to identify the associated factors.

Methods An analytical cross-sectional study of data from the 2019 Peruvian Demographic and Family Health Survey (Encuesta Demográfica y de Salud Familiar, ENDES, in Spanish) was conducted. The dependent variable was adequate compliance with ANC (provided by skilled health care professionals; first ANC visit during the first trimester of pregnancy; six or more ANC visits during pregnancy; ANC visits with appropriate content) by women aged 15 to 49 years in their last delivery within the five years prior to the survey. Crude and adjusted prevalence ratios and their 95% confidence intervals were calculated using a log-binomial regression model.

Results A total of 18,386 women were analyzed, 35.0% of whom adequately complied with ANC. The lowest proportion of compliance was found with the content of ANC (42.6%). Sociodemographic factors and those related to pregnancy, such as being in the age groups of 20 to 34 years and 35 to 49 years, having secondary or higher education, belonging to a wealth quintile of the population other than the poorest, being from the Amazon region, not being of native ethnicity, having a second or third pregnancy, and having a desired pregnancy, increased the probability of presenting adequate compliance with ANC.

Conclusion Only 3 out of 10 women in Peru showed adequate compliance with ANC. Compliance with the content of ANC must be improved, and strategies must be developed to increase the proportion of adequate compliance with ANC.
Introduction

Maternal mortality still occurs in different parts of the world, despite a marked reduction from 385 to 216 deaths per 100 thousand births between 1990 and 2015. Therefore, the United Nations (UN) Sustainable Development Goals (SDGs) are a blueprint established with the aim of reducing global maternal mortality to a figure lower than 70 per 100 thousand births, especially in low and middle-income countries, which account for almost all deaths.

Antenatal care (ANC) is considered vital to reduce maternal and neonatal morbidity and mortality. According to the World Health Organization (WHO), ANC includes the treatment of pregnancy symptoms, nutritional consultations, evaluations of the mother and fetus, and improvement in health care services directed to the mother and the fetus. Nonetheless, the literature consulted shows differences among countries regarding the number of ANC visits and compliance with ANC.

Latin America and the Caribbean are among the regions with the highest maternal mortality. However, the number of deaths in these regions has decreased in recent decades (from 124 to 69 per 100 thousand live births in Latin America, and from 276 to 175 per 100 thousand births in the Caribbean). Nevertheless, no country in this region has reached the goal of reducing maternal mortality by 75%. In the case of Peru, maternal mortality has decreased from 265 to 68 per 100 thousand live births between 1990 and 2015. Despite this clear reduction, in 2019, the maternal mortality rate in Peru was 56.1 per 100 thousand births, indicating a scenario in which pregnancy-related deaths remain a public health problem.

The Peruvian Ministry of Health (Ministerio de Salud, MINSA, in Spanish) has established that skilled health care professionals perform adequate ANC with at least six ANC visits, the first of which is made during the first trimester of pregnancy. ANC includes guidance and counseling for pregnant women, tests to support diagnosis and prophylaxis, prenatal stimulation, individual psychological consultation, dental consultation, nutrition consultation, as well as social services and legal consultations. To date, adequate compliance with ANC according to the MINSA and WHO recommendations has not been studied among pregnant women in Peru. Therefore, the objective of the present study was to determine the adequacy of compliance with ANC and to identify factors associated with compliance in Peru.

Methods

Study Design and Population

A cross-sectional and analytical study of the data of women and their last delivery within the five years preceding the completion of the 2019 ENDES was conduct. The present manuscript was written following the guidelines of the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) statement.

Resumo

Objetivo Determinar a adequação do cumprimento dos cuidados pré-natais (CPN) por mulheres grávidas no Peru e identificar os fatores associados.

Métodos Foi realizado um estudo analítico transversal dos dados da Pesquisa Demográfica e de Saúde da Família Peruana de 2019 (Encuesta Demográfica y de Salud Familiar, ENDES, em espanhol). A variável dependente foi conformidade adequada com a CPN (forneccida por profissionais de saúde qualificados; primeira visita CPN durante o primeiro trimestre de gravidez; seis ou mais visitas CPN durante a gravidez; visitas CPN com conteúdo apropriado) por mulheres de 15 a 49 anos em seu último parto nos cinco anos anteriores à pesquisa. Os índices de prevalência bruta e ajustada e seus intervalos de confiança de 95% foram calculados usando um modelo de regressão log-binomial.

Resultados Foi analisado um total de 18.386 mulheres, das quais 35,0% cumpriram adequadamente o CPN. A menor proporção de conformidade foi encontrada com o conteúdo de ANC (42,6%). Fatores sociodemográficos e aqueles relacionados à gravidez, como estar na faixa etária de 20 a 34 anos e 35 a 49 anos, ter educação secundária ou superior, pertencer a um quintil de riqueza da população que não a mais pobre, ser da região da selva, não ser de etnia nativa, ter um segundo ou terceiro filho e tendo uma gravidez desejada, aumentou a probabilidade de apresentar conformidade adequada com CPN.

Conclusão Apenas 3 em cada 10 mulheres no Peru mostraram conformidade adequada com o CPN. O cumprimento do conteúdo do CPN deve ser melhorado, e estratégias devem ser desenvolvidas para aumentar a proporção de cumprimento adequado com o CPN.
According to its geographic characteristics, Peru is divided into three regions differentiated by geographic, climatic, and sociodemographic aspects. The Coast region borders the Pacific Ocean, and it is where Lima, the capital of the country, is located. The Andean region has the highest levels of altitude and the population with the lowest level of wealth in the country. Lastly, the Amazon is the region with the greatest biodiversity; however, its population does not have adequate access to health services due to geographic limitations regarding access.\footnote{11}

The ENDES is a population-based survey conducted by the National Institute of Statistics and Informatics (Instituto Nacional de Estadística e Informática, INEI, in Spanish), which provides information on the sociodemographic and health characteristics of the population. It uses complex sampling in two stages: the first is the selection of clusters, and the second, of households. It is representative of urban and rural areas throughout Peru according to the geographic (Coast, Andean, and Amazon) and administrative regions. The ENDES uses direct interviews to collect data, and these are performed by trained personnel who visit the selected homes to fill out three questionnaires (a household questionnaire, for households and their members; an individual questionnaire, for all women of childbearing age; and a health questionnaire applied to the head of the household, which collects information on household characteristics, for persons 15 years of age or older). Detailed information on the sampling, collection, and processing of ENDES data are available on the INEI website.\footnote{12}

**Variables and Measurements**

The dependent variable was adequate ANC compliance in the last pregnancy by women aged 15 to 49 years within the 5 years preceding the date of the survey. The ANC was considered adequate when fulfilling the following aspects: performed by a skilled healthcare personnel (doctors, nurses, or midwives, as reported in the ENDES data);\footnote{2} first visit before the end of the first trimester of pregnancy; six or more visits during pregnancy; and visits including all of the required services (with appropriate content). Non-completion of these aspects was considered as inadequate compliance. These components of adequate compliance with ANC have been previously used by other studies in the literature.\footnote{5-7} The content of the ANC visits evaluated was based on the WHO recommendations,\footnote{3} considering only the data of pregnant women participating in the survey (the WHO recommends including the measurement of blood pressure; urine and blood analysis, HIV and syphilis testing, administration of iron tablets, protection against tetanus, and information on pregnancy complications and where to go if they occur). The absence of any of these features in ANC visits was considered as non-compliance. For the present study, the minimum number of ANC visits required was six, as established by the MINSA in 2013 for the care of pregnant women in Peru.\footnote{9}

According to the literature, the independent variables considered to be associated with adequate compliance with ANC\footnote{3-7,13} are: maternal age ([V012]: 15 to 19 years; 20 to 34 years; 35 to 49 years); level of schooling ([V106]: no education or primary education; secondary education; higher education); wealth quintile ([V190]: very poor; poor; intermediate; rich; richest); geographic region (SHREGION: Metropolitan Lima; rest of the Coast; Andean; Amazon); area of residence ([V025]: urban; rural); having public health insurance ([S413]: yes; no); ethnic self-identification ([V131]: non-native; native); birth order ([BORD]: first birth; second or third births; \(\geq\) fourth birth); desired pregnancy ([M10]: yes; no); and type of pregnancy (B0: multiple; single).

**Statistical Analysis**

The 2019 ENDES databases were imported, combined, and analyzed using the Stata (StataCorp., LLC, College Station, TX, US) software, version 16. In every analysis, the weighting factors and specifications of the complex sample design of the ENDES were considered, using the svy command in the Stata software. Likewise, values of \(p < 0.05\) were considered statistically significant for all statistical tests.

Sociodemographic characteristics and those related to the last pregnancy of the study population were reported using absolute frequencies and weighted proportions for the categorical variables, and averages with standard deviations for the numerical variables. Likewise, the spatial distribution of adequate compliance with ANC was represented according to the administrative regions of Peru (HV023: [24 departments and the constitutional province of Callao]).

To evaluate the association of the sociodemographic variables and those related to the last pregnancy with adequate compliance with ANC, prevalence ratios (PRs) and their 95% confidence intervals (95%CIs) were calculated using a log-binomial regression model. Finally, a multivariate analysis was performed to estimate the adjusted PR (aPR) for all independent variables with statistically significant values in the crude analysis.

**Results**

The data of 18,386 women who had delivered a child in the 5 years preceding the study were analyzed (\(\rightarrow\)Fig. 1).

Regarding the sociodemographic characteristics of the women analyzed (\(\rightarrow\)Table 1), 45.7% had a secondary education as their level of schooling, and 18.7% had no education or had only reached the primary level. Most of the women lived in the Coast region (56.2%). In addition, 74.8% lived in urban areas. Regarding health insurance, 67.2% had comprehensive health insurance (seguro integral de salud, SIS, in Spanish). In relation to ethnic self-identification, 6.3% reported belonging to a native ethnic group. Regarding pregnancy, 33.6% declared that they had had their first delivery; half of the women reported having had 2 or 3 deliveries, and 46.2% said that their last birth was an unwanted pregnancy. With respect to the type of pregnancy, less than 1% (0.9%) had a twin pregnancy.

The ANC visits were adequate in 35.0% of the women analyzed (\(\rightarrow\)Table 2). Based on the administrative regions of
the Peruvian territory, in general, the lowest proportions of ANC visits were found in the Andean region (Fig. 2). According to the services included in adequate ANC, almost all women (98.3%) were cared for by skilled health care personnel. The first ANC visit was in the first trimester of pregnancy for 81.10%, and 89.70% underwent six or more visits. Regarding compliance with the content of ANC as stipulated by the MINSA, 42.6% of the women underwent ANC visits with appropriate content.

In relation to the analysis of the association between sociodemographic variables and adequate compliance with ANC (Table 3), we found that women in the age groups of 20 to 34 years (aPR: 1.38; 95% CI: 1.19–1.60) and from 35 to 49 years (aPR: 1.36; 95% CI: 1.16–1.61) had a higher probability of presenting adequate compliance with ANC compared with adolescent pregnant women. Regarding the level of schooling, women with secondary (aPR: 1.19; 95% CI: 1.10–1.29) or higher education (aPR: 1.17; 95% CI: 1.06–1.30) had a higher probability of having adequate ANC compared with those with no education or only primary education. According to the wealth quintile, poorer women (quintile 1) were generally less likely to have had appropriate ANC compared with those in quintile 2 (aPR: 1.12; 95% CI: 1.02–1.23) and quintile 3 (aPR: 1.18; 95% CI: 1.06–1.31). As for the geographic domain, in the Andean region, women were less likely to receive proper ANC compared with those from the Coast region (aPR: 0.73; 95% CI: 0.67–0.79), while women from the Amazon region were more likely to have adequate ANC compared with those from the Coast (aPR: 1.26; 95% CI: 1.17–1.35). No significant differences were found between women in rural and urban areas concerning the probability of presenting adequate compliance with ANC (p = 0.188). Regarding ethnic self-identification, women of native ethnicity were less likely to have adequate ANC (aPR: 0.83; 95% CI: 0.71–0.96).

Regarding the variables related to the last pregnancy and their association with adequate compliance with ANC (Table 3), women in older age groups had a higher probability of presenting adequate compliance with the ANC visits. A significant difference was observed between women with
a second or third birth compared with those delivering for first time (aPR: 0.92; 95%CI: 0.87–0.98). There was no difference in adequate compliance with ANC between women who had a first birth or those with four or more births \( (p = 0.070) \). Women with an unwanted pregnancy had a lower probability of adequate compliance with ANC (aPR: 0.82; 95%CI: 0.78–0.86). On the other hand, there were no differences between women who had a single birth compared with those with multiple births in relation to adequate compliance with ANC \( (p = 0.800) \).
Antenatal care is a strategy that is promoted throughout the world to improve maternal health, and it is included in the Peruvian regulations for the adequate care of pregnant women. However, the results of the present study indicate that less than half of pregnant women in Peru received adequate ANC during the five years prior to the 2019 ENDES survey. The component with the lowest ANC compliance was the provision of the complete ANC content (care by skilled health care personnel, the first visit made before the end of the first trimester of pregnancy, and six or more ANC visits during pregnancy). Likewise, the sociodemographic factors, such as age, level of schooling, well-being index, ethnicity, and region of origin, as well as factors related to pregnancy, such as the order of the number of deliveries and desired pregnancy, were associated with non-compliance with ANC.

The 2019 ENDES showed that only 3 out of 10 pregnant Peruvian women presented adequate compliance with ANC, and the lowest proportion of compliance was regarding the fulfillment of all the content required to receive an adequate ANC (4 out of 10). In a study performed in 2019,14 1 in 2 pregnant women received ANC with adequate compliance to the content, which is similar to the findings of the present study. Similarly, in low and middle-income countries, low proportions of compliance with the contents of ANC have been reported.5–7 In relation to maternal health, in recent decades, there has been an increase in the number of ANC visits per pregnant women, as well as in ANC provided by skilled health care personnel.13 Likewise, in Peru, ANC provided by skilled health care personnel has increased from 54.6% (1986) to 98.2% (2019).14 These increases are consistent with the global panorama, which reveals an increase in the number of ANC visits, as well as in the proportion of women who start ANC early, and in the care provided by skilled health care personnel.15 Given the widely-studied relationship between inadequate ANC and the presence of negative maternal and perinatal outcomes, such as maternal and fetal death or low birth weight,16,17 it is necessary to strengthen ANC in Peru. Improvements in ANC should include not only sustaining the rise in the number of pregnant women cared for by skilled health care personnel with an adequate initiation and number of ANC visits, but also strategies to enable the recruitment of pregnant women who are not yet receiving this care, as well as to improve compliance with ANC content during pregnancy.

In relation to sociodemographic factors, we found that the higher the level of education, the more likely the mother was to present adequate compliance with ANC, and that women with a higher level of schooling were more likely to adequately comply with ANC visits, which is similar to what has been described worldwide.5–7,18–20 It has been observed that women with a higher level of schooling tend to value more the ANC, which would explain the greater adequate compliance with ANC in this group. Similarly, several studies5–7,21 have shown that women with a higher socioeconomic status are more likely to receive adequate ANC and even a larger number of services. In Peru, the SIS provides free public insurance that covers ANC visits and childbirth for every woman in the Peruvian territory who does not have another...
One of the findings of the present study was that women with SIS showed a higher proportion of adequate compliance with ANC. The results of the present study describe a scenario in which, despite ANC visits and ANC content being covered and regulated for all women in the Peruvian territory, adequate ANC differs according to the level of schooling and the socioeconomic level, as well as having health insurance.

**Abbreviations:** aPR, adjusted prevalence ratio; CI, confidence interval; PR, prevalence ratio.

**Note:** A generalized linear model of the binomial family was performed for complex samples. Variables with a p-value < 0.05 in the bivariate analysis were included.
Regarding the geographic domain, women from the Andean region were less likely to adequately comply with ANC compared with those from the Coast. In the five years preceding the study, the proportion of women seen in the first trimester increased; however, in 2018, a lower proportion of women from the Andean region had their first ANC visit during this period compared with those from the Coast region (74.8% versus 84.6%, respectively). On the other hand, women from the Amazon region were more likely to have ANC with adequate compliance compared with those from the Coast region. Similarly to the Andean region, there has been an increase in the proportion of women in the Amazon region undergoing ANC visits in recent years, as well as in the number of those who started ANC during the first trimester of pregnancy. Nonetheless, Peruvian women from the Andean and Amazon regions have the highest proportion of maternal mortality in the country; therefore, increased efforts are needed to develop strategies to reduce this health indicator.

There were no differences between women living in rural areas and those living in urban areas in relation to less adequate compliance with ANC. In recent years, the proportion of rural women who have undergone an ANC visit during the first trimester has increased, in addition to the number of visits received and other useful strategies to reduce maternal mortality, such as institutionalized delivery. However, there is still a gap between women in urban and rural areas regarding ANC. A similar situation has been observed throughout the world, and it has been reported that rurality is associated with an increase in maternal mortality. Taking into account that the area of residence is related to ANC onset and delay, joint efforts are needed to sustain the increase in the number of ANC visits received by women in rural areas and to achieve adequate compliance with ANC, to contribute to reduce morbidity and mortality in both the mother and the fetus.

Regarding the age of the pregnant women, the probability of having adequate ANC increased with age. Previous studies performed in other countries report that the older the pregnant woman, the more likely she is to receive adequate ANC. A previous study have reported that there was no difference between the age groups of women of childbearing age in terms of receiving the required ANC content. A possible explanation for why older women have greater adequate compliance with ANC could be that they may be considered as being at a greater risk by health care personnel, or that the experience of previous pregnancies sensitizes these women about the importance of undergoing ANC visits, thereby increasing the likelihood of adequate compliance. Regarding ethnic identification, self-identified native women were less likely to adequately comply with the ANC visits. In Latin America and the Caribbean, a lower proportion of women of native ethnic groups have access to ANC and delivery care provided by skilled health care personnel compared to women of non-native ethnic groups, with reports of difficulties in the implementation of programs to increase the number of women of native ethnic groups receiving ANC.

In relation to the characteristics of the pregnancy, women with four or more previous deliveries had a lower probability of presenting adequate compliance with ANC. Some studies performed in other countries describe that the greater the number of births a woman has had, the less likely she will attend ANC visits, possibly due to the feeling of security that the experiences of the previous births bring her. On the other hand, studies have observed that women with an unwanted pregnancy are less likely to adequately comply with ANC or to start ANC controls early, because of they have less interest in this care. These results could explain the differences found in the present study. In Peru, there is an unmet need for family planning, and women have difficulty preventing unwanted pregnancies, in addition to the social stigma of continuing with a pregnancy when they are in a socially-undesirable personal situation or undergoing an abortion (which occurs at a high rate, despite being illegal in the country, except for medical reasons). Unwanted pregnancies are described in the literature as associated with an increased risk of maternal and neonatal health complications, among other adverse outcomes, including a higher risk of cesarean sections, inappropriate weight gain, and mental health disorders. These characteristics associated with non-compliance with ANC indicate which population subgroups of women of childbearing age would not receive adequate ANC in accordance with the WHO recommendations and Peruvian standards, and a major concern of decision-makers is the achievement of adequate compliance with ANC in these women.

In regard to the limitations of the present study, since it is a study of secondary data, it is likely that some of the data may not be adequate. Another limitation of the study related to the ENDES is the possibility of introducing a recall bias and the lack of understanding of some questions by the respondents, a situation that is typical of any study based on surveys that collect data on past events. In addition, the ENDES does not record data on diseases or risk factors for women that could be of great use to health services, including ANC visits. However, the ENDES has protocols that ensure the quality of the recorded data, and it is widely used by public institutions and researchers as a source of information for the development of research and decision-making regarding health care in Peru. Moreover, it is a survey of national and regional representation, which records data that are used to evaluate adequate compliance with ANC based on the recommendations of the WHO and regulated by the MINSA.

**Conclusion**

In conclusion, in 2019, we observed that 3 out of 10 women in Peru presented adequate compliance with ANC, as recommended by the WHO and the MINSA standards. In relation to the components of adequate compliance with ANC, only 4 out of 10 women had undergone ANC that included the required care content. In addition, population subgroups, such as women from the Andean region and rural areas, native ethnic groups, and those with lower level of schooling
and socioeconomic status were less likely to present adequate compliance with ANC. These findings reveal the need to strengthen ANC among the Peruvian population, with an emphasis on providing the required content during care and developing strategies for population subgroups with a lower likelihood of having adequate compliance with ANC.

Ethical Considerations

The Institutional Research Ethics Committee of Universidad Científica del Sur approved the present study (under registration code: 349-2019-PRE15).
