While atrial septal defect (ASD) classifies as the most common cause of grown-up congenital heart (GUCH) disease, it can present with unconventional symptoms, owing to the underlying pathophysiological alterations. 1 Atypical chest pain in ASD can be due to arrhythmias, right ventricular dysfunction, or ischemia. However, we describe an interesting echocardiographic finding, showcasing a rare potential cause of left main coronary artery (LMCA), resulting in chest pain in patients with ASD.

Although asymptomatic survival to adulthood is common, patients can present with pulmonary arterial enlargement, owing to varying degrees of pulmonary arterial hypertension. This can result in grossly distended pulmonary arteries. The left main coronary artery arises just above the left Sinus of Valsalva and courses behind the pulmonary trunk. It travels for a very short distance along the epicardium between the pulmonary trunk and aorta before dividing into anterior descending and circumflex arteries. 2 The expansion of pulmonary artery can manifest as a cause of extraluminal/dynamic LMCA compression. 3, 5 This can masquerade as ischemic heart disease, despite the absence of any coronary artery atherosclerosis.

We hereby present a case of a 40-year-old female with complaints of chest pain who was brought to the Cardiotoracic Intensive Care Unit (CTVS ICU) when she developed ventricular ectopics and ST segment changes on EKG monitoring. The transesophageal echocardiography (TEE), performed using Philips Epiq 7 (Bothell, WA) X7–2T

TEE Probe (2–6 MHz), revealed a large ostium secundum ASD measuring 4.2 cm with left-to-right shunt. The patient had dilated right atrium (RA), right ventricle (RV), left atrium (LA), and pulmonary artery (PA). On midesophageal aortic valve short axis (SA) view (► Fig. 1), the LMCA appeared to be significantly narrowed (diameter—0.24 cm). The PA, in the midesophageal ascending aortic SA view (► Figs. 2 and 3), was grossly dilated (diameter—3.8 cm), dynamically compressing the LMCA. The dynamic compression is evident in this view, as seen in the video clip (► Video 1). The TEE findings were subsequently confirmed using CT angiography, and the patient was planned for ASD closure with coronary artery bypass graft (CABG) surgery. ASD closure using dacron patch and left internal mammary artery to left anterior descending artery graft was performed. Following the surgery, patient was placed on mechanical ventilation in ICU for 8 hours and then successfully extubated with no adverse events.
