Background
With rising incidence and increased life expectancy of patients with chronic kidney disease (CKD) and end-stage renal disease (ESRD), the number of patients requiring hemodialysis has increased substantially. Vascular access is the lifeline for a patient on hemodialysis (HD), and an arteriovenous fistula (AVF) is the undisputed gold standard for HD access. An effective and long-lasting fistula serves to increase the life expectancy of ESRD patients and improves their quality of life.

Learning Objectives
This paper aims to give a comprehensive overview of AVF creation, including the various techniques, patient selection, troubleshooting with decision-making, and common complications. Authors share their experience from previous publications and over 2000 AVF surgeries. They have not only described a new modification of the technique of proximal fistula but have also established a direct correlation between bruit and thrill on operation table and success of fistula surgery.

Conclusion
A standardized, protocol-driven multidisciplinary approach with careful patient and site selection, guided by outcome predictors, is vital in AVF surgery. Knowledge about the potential complications of AVFs contributes to their timely detection and allows measures to be taken that might prevent deleterious consequences that range from loss of vascular access to serious morbidity and mortality.

Abstract

► ESRD

Introduction
The estimated prevalence of chronic kidney disease (CKD) in India is 17.2%, with approximately 130,000 patients on dialysis and annual growth of 10 to 20%.1-4 In patients on long-term renal replacement therapy (RRT), the major challenge is inadequate dialysis facilities & support systems, non-affordability, vascular access issues, and lack of surveillance systems, leading to a high dropout rate. Vascular access is the lifeline for a patient on hemodialysis (HD), aptly described as the Achilles heel due to associated morbidity.5,6 By creating an effective and long-lasting arteriovenous fistula (AVF), we can improve life expectancy and quality of life for these patients.

Only 9 to 13% of CKD patients in need of HD have AVF created before initiation of dialysis.7 A holistic multidisciplinary center with monitoring and surveillance programs goes a long way to achieve this objective. Primary physicians or nephrologists have to consider the resources, longevity, and affordability of patients before recommending AVF. It is imperative to identify the site and preserve the veins by avoiding venipuncture.
Ideal Vascular Access and Options

International guidelines and various study groups such as National Kidney Foundation-Kidney Disease Outcomes Quality Initiative (NKF-KDOQI) 2006 CPG 2.1 (Clinical Practice Guidelines), European Best Practice Guidelines, and Canadian Society of Nephrology recommend autogenous, native vessel AVFs over the central venous catheters (CVCs) for initiation of HD.\(^8\) Patients who receive dialysis across a functional AVF have lower complication rates and longer duration of event-free patency than with catheter access and arteriovenous grafts (AVGs).\(^9\,11\) The ideal AVF should have early placement, easy accessibility, minimal primary failure rates, early maturation, long-term patency, and minimal complications. Despite a reported failure rate of 7 to 40% with an average of 15.3%, a well-made AVF lasts as long as 10 to 12 years when used carefully.\(^16\,17\)

The order of preference of NKF-KDOQI guidelines suggest radiocephalic, brachiocephalic, and brachiobasilic transposition fistulae and then prosthetic grafts as vascular access options.\(^8\,9\)

Arteriovenous Fistula

Brescia, Cimino, Appell and Hurwich (1966—New York, US) created the first surgical subcutaneous side-to-side AVF between radial artery and adjacent superficial vein and published a landmark series of 14 patients.\(^18\) Cimino fistulas are currently accepted as the ideal mode of vascular access for HD. Various factors which guide the timing of fistula creation are summarized in Table 1.\(^8\,9\) “Fistula first” initiative was implemented as the national vascular access improvement initiative, with a goal to create AVF in 50% of newly diagnosed CKDs, and to have a functioning AVF 6 months before the anticipated need for HD.\(^8\,9\,20\)

Preoperative Evaluation

The history of recent venous injections for blood sampling or intravenous (IV) access must be accurately recorded. Any associated comorbidities like diabetes, vascular disease, history of multiple central venous catheters, collagen vascular disease, etc. should be noted (Table 2).

Patient’s ability to lie supine for a period of 1 to 2 hours without suffering from breathlessness is crucial. In cases of fluid overload with orthopnea, it is advisable to dialyze the patient the day before the procedure. Clinical evaluation should include both arterial and venous assessment (Table 3). The superficial venous system should

Abbreviation: AVF, arteriovenous fistula.

To be mapped with an outflow obstruction, using a tourniquet at the upper arm. Preferably, a straight segment should be marked, checking the compressibility, distensibility, emptying, and evidence of needle pricks or thrombophlebitis.

Although NKF guidelines advise preprocedure objective Doppler evaluation in all cases, we prefer to selectively do it only when clinical findings are inconclusive or doubtful.\(^8\,9\) Central venous stenosis is clinically evident by dilated superficial veins in the axilla and lateral torso and confirmed by a Doppler examination.\(^20\)

For patients with unsuitable and nondiscernible veins who are unlikely to improve with physiotherapy, the decision to do a proximal fistula should be made if early availability of vascular access is required.

Decision Making for Fistula Creation

Proximal Versus Distal AVF

The preferred sequence is distal fistula in a nondominant hand, followed by proximal brachiocephalic, and brachiobasilic fistula with or without primary vein transposition. In case of failure or nonavailability of nondominant hand, the same sequence is followed in the dominant hand. Although the proximal or brachiophlebic fistulae have lesser primary failure rates and faster maturation, they have a higher
complication rate, such as persistent distal edema, steal phenomenon, and aneurysm formation. It is essential to advise patients and caregivers on protecting the proposed extremity from needle pricks and IV accesses.

End-to-Side Versus Side-to-Side
End of vein to side of artery anastomosis has minimum postoperative complications like distal swelling, necrosis, or ulcerations.23 In side-to-side fistula creation, authors have described a modified technique of side-to-side brachiobasilic fistula with equivalent results.24,25 It involves manual distal valve dysfunction with a vein dilator, which leads to development of forearm veins for HD access, thereby avoiding long incision for vein transposition and its complications. Basile vein can be superficialized secondarily, if and when forearm veins become unusable, as a backup plan, without the need to create a new fistula.

The final decision on whether to opt for an end-to-side or a side-to-side anastomosis is predominantly guided by surgeon preference and local anatomical factors.

Operative Technique
Surgical creation of AVF is a day care or an outpatient procedure done under local anesthesia and loupe magnification without a tourniquet control.

Distal AVF (Radiocephalic)
A 2.5 to 3 cm S-shaped incision is marked (►Fig. 1 A) for adequate exposure and with a provision to extend it proximally along the course of the vein if required. Around 10 mL local anesthetic is infiltrated (2% plain lignocaine), taking care not to puncture the vein. The cephalic vein and radial artery are dissected, preserving the superficial radial nerve (►Fig. 1 B)

The geometry of the anastomosis, that is the angle at which the vein meets the artery at site of fistula, is an important predictor of the flow and maturation.26 It is advisable to keep vein to artery angle as acute as possible (18°) to have an optimum flow across the fistula and minimum wall shear stress.27 Backflow from the vein and its lie is checked and confirmed before anastomosis. If the artery is atherosclerotic, noncompressible segment should be avoided while selecting site of arteriotomy. After securing vascular double clamps in position, an arteriotomy of approximately 6 to 7 mm in length is done with an 11 number surgical blade or microscissors. Anastomosis is done either in continuous or interrupted fashion with 7–0 polypropylene or 8–0 monofilament nylon. Care is taken to clip the side branches of the vein, so as to prevent the development of accessory veins and distal limb complications. Any fibrous or fascial band compressing the outflow segment of the vein is released. Skin is closed with single-layer interrupted sutures after confirming hemostasis. A noncompressible and noncircumferential dressing is given.

Proximal AVF (Brachiocephalic fistula)
The technique and operative principles of an end-to-side proximal AVF creation are similar to the distal radiocephalic fistula with a few differences (►Fig. 2) The arteriotomy size is reduced to approximately 5 to 6 mm because of the higher flow at brachial artery and so as to prevent any steal phenomenon and distal complications.

Proximal AVF (Brachiobasilic Transposition Fistula) and Basilic Vein Superficialization
In cases where cephalic venous system is unavailable or unsuitable for the fistula creation, basilic vein can be used. The basilic vein by virtue of its subfascial location in arm is naturally protected from damage caused by venipuncture. However, due to its deeper location, vascular access is difficult; therefore, it needs to be superficialized in the subfascial plane and transposed anteriorly in line of cephalic vein, either in the same sitting or after maturation.

The surgical technique of superficialization includes taking a long linear incision on medial aspect of the arm, safeguarding the medial cutaneous nerve of forearm. As there are hardly any major tributaries present in this course of the vein, dissection is easy, vein is transposed anteriorly in the subcutaneous plane, and fascia is closed beneath the vein, thus superficializing it (►Fig. 3).
Nuances of Arteriovenous Fistula Creation
Sahasrabudhe and Bindu

The advantages of this procedure are that it produces a long length of the straight superficial vein with a high flow rate. However, the disadvantages include need for long length of incision, increased chances of hematoma formation, requirement of regional or general anesthesia, long duration of surgery, increased stay in the hospital, and thus increase in requirement of regional or general anesthesia, long duration of incision, increased chances of hematoma formation, and increased chances of lymphorrhea and wound infection.

Author’s Modification
We have modified the technique of proximal brachiobasilic fistula to address the limitations of the conventional technique (Table 4). We perform a side-to-side anastomosis between the brachial artery and basilic or median cubital vein at elbow. After completion of the posterior wall of the anastomosis with 7-0 polypropylene, a long arm vessel dilator is introduced into the distal part of the basilic/antecubital vein to dysfunction the first valve toward the wrist end. This allows retrograde flow in the distal vein toward the forearm, which is confirmed by flushing it with heparinized saline and looking for thrill on the forearm. Once this flow is confirmed, the anterior wall anastomosis was completed.

The Endpoint of Surgery on the Operation Table
After completing the anastomosis, the patency and flow are confirmed by filling up the vein and palpation of thrill. Return of distal pulsations and hand vascularity is confirmed after releasing the clamps. The authors established a direct correlation between the presence of bruit heard on the table and thrill felt at the end of surgery with long-term patency and maturation of AVF.

Postoperative Care
Patients and their relatives are instructed to avoid venipunctures on the operated side, blood pressure cuffs, tight clothing or ornaments, and any prolonged pressure. Handball exercises are taught to patients before discharge. Further, they are taught to feel the thrill every day and report to the surgeon immediately if the thrill disappears and are counseled about the warning signs like coldness, numbness, ulcers, or discoloration at fingertips. Anticoagulation is given in the form of single dose of low-molecular weight heparin (LMWH) (1 mg/kg body weight). Patients are called for review at around day 3 for first follow-up and then on 10 to 12 days where the thrill is assessed and sutures are removed, and again reviewed at 4 weeks, for features of maturation.

Mature and Useable Fistula – Characteristics and Guidelines
Primary fistula failure is defined as poor blood flow across a fistula (< 250 mL/min) not sustained for a minimum of 3 hours even after to 12 weeks of its creation. Average time taken for the fistula to mature is 4 to 6 weeks. The flow across the fistula multiplies to five to 10 times that of the normal arterial flow. Intraoperative flow measurements immediately after fistula creation are also a good predictor to assess the eventual maturation of an AVF. The average time a nephrologist advises the fistula to be used for the HD is 6 to 8 weeks, in accordance with the rule of 6 proposed by KDOQI (Table 5). The main reason for the failure of maturation of a functioning fistula is undiagnosed central venous stenosis or proximal obstruction. Such cases do benefit from addressing the underlying cause by endovascular techniques.

Troubleshooting for Fistula Surgery
1. No backflow from the vein
Having a good backflow from the proximal end of the vein is a good predictor of proximal patency and continuity with central veins, although it is not an absolute prerequisite. Palpating for a thrill when the vein is flushed with heparinized saline with a blunt 24 G IV cannula tip with a 5 mL syringe is a good maneuver to confirm the same and rule out central venous stenosis in case of the absence of backflow.

2. No pulsations or thrill or bruit
Absence of any pulsations or thrill postanastomosis indicates a technical problem like including the backwall in a suture, inadequate adventectomy, severe torsion or kink, or too much traction on the vessels, due to improper siting of the arteriotomy, soft thrombus at the anastomosis, a fascial band compressing the vein causing outflow obstruction, or a proximal obstruction.

3. Role of anticoagulation
Authors have shown that there is no proven role of long-term postoperative heparin or aspirin in long-term patency rates, where the anastomosis was satisfactory with good thrill and bruit on table.30

4. Early Fistula Failure or Loss of thrill
The absence of well-developed dilated veins for HD access or disappearance of thrill within 3 months of postoperative period or prior to maturation of fistula is termed as early fistula failure.31 Various clinical predictors which predispose to early fistula failure are small caliber vessels (artery < 2 mm and vein < 2 mm), distal AVFs, female gender, obesity, diabetes, vascular disease, suboptimal blood flow on the table or on the first postoperative day, and surgeon-related factors of skill and experience.24,32,33 (~Table 6).

Interventional radiologists can also play a role in salvaging an early as well as late failing fistula due to thrombosis or stenotic lesions, with thromboembolectomies or dilatations by endovascular techniques, but their application is limited because of cost constraints.34-37

Predictors of Outcome- Factors Affecting Fistula Maturation and Patency Rates
In our study of patency and outcomes of 505 AVFs using logistic regression with success and immediate failure as the dependent variables, we have drawn various conclusions and recommendations, which are as follows:24

1. Presence of on table thrill and bruit has a direct and statistically significant relation with success and maturation of fistulas.
2. Patients with vein diameter < 2 mm are 5.4 times more prone to fistula failure.
3. There is no significant association between side of arm used, site of fistula creation, type of anastomosis and suture material, and success rate.

4. Postoperative long-term anticoagulation has no major beneficial role in eventual patency rates in uncomplicated fistula surgery.

Long-Term Complications
Distal limb edema, ulcerations, gangrenous fingertips, limb hypertrophy, and lymphorrhea.

The occurrence of swelling or edema in the distal extremity is one of the more commonly seen complications in side-to-side fistulas. This may predispose to distal necrosis and ulcerations too due to venous hypertension. Persistent hyperdynamic circulation and venous hypertension may also lead to limb hypertrophy in chronic setting, needing fistula closure in severe cases.38

In cases of proximal brachiocephalic or brachiobasilic fistula with vein transposition, the medial lymphatic outflow track may be damaged due to dissection and long incision and may predispose to lymphedema distally or lymphorrhea at elbow in rare cases, which is usually self-limiting and managed conservatively. Distal edema can be managed with limb elevation, gentle compression dressings, and physiotherapy with antegrade massage in most cases. In selected cases, surgical ligation of accessory veins might be necessary to limit the distal runoff, which can be performed transcutaneously.

Aneurysm and Pseudoaneurysm Formation
Aneurysms and pseudoaneurysms are localized vascular dilatations which can either be venous or arterial. Venous aneurysms generally occur at the site of needle pricks due to repeated punctures at the same site, as done in the button-hole technique (preferred as less painful) of pricking a fistula.39 It is advised to follow the step ladder technique, where the prick site is changed to avoid this complication. They should be evaluated for impending rupture with skin ulcerations and ligated and excised electively under tourniquet control and regional anesthesia.

Steal Phenomenon/Ischemic Steal Syndrome
The steal phenomenon entails that the blood from the artery flows preferentially into the low-pressure venous system through the fistula rather than to the distal arterial bed, creating a zone of distal arterial insufficiency.40,41 It is common in patients with severe atherosclerosis, in arteries distal to AVF site (especially in proximal AVF), and in diabetic patients.42

Thrombosis/Stenosis of Fistula
KDOQI guidelines define significant stenosis of the vessel lumen as a reduction by more than 50%.19 Stenosis can also occur due to extraluminal compression by an abscess, hematoma, or seroma. Clinical suspicion of stenosis is confirmed by the presence of several factors like reduced quality of dialysis, prolonged bleeding after AVF puncture, pain in the area of the fistula, or increased venous pressure. Various options available to deal with these complications are thromboembolectomy, angioplasty with or without stenting, or surgical creation of a new fistula.

Table 6 Etiological factors for fistula failure

Abbreviation: AVF, arteriovenous fistula.
Cardiac Overload and Failure
Cardiac complications are better avoided than managed by careful preoperative patient selection. They are more commonly seen in patients with preexisting chronic heart disease (low-ejection fraction [EF]) and large diameter fistulas.43 The salvage of failing fistula by radiological interventions has a high immediate technical success rate but a 1 year patency rate of 32%, needing multiple interventions for salvage and functionality (3.3 procedures per fistula); thus, it may not be cost-effective.43,45,46 We prefer to perform a new fistula when the previous has failed or has inadequate flow rates on HD, as the morbidity, longevity, as well as costs for radiological fistula salvage are inferior when compared with new fistula creation.

Recent Advances and Other Options
Gracz Arteriovenous Fistula
Gracz AVF was described at the elbow with equivalent results and patency rates to conventional side-to-side fistulas.45 The anastomotic site is below the elbow crease. The perforating vein between the superficial (median cubital or cephalic) and deep venous system is disconnected and its end is anastomosed in end-to-side fashion to brachial artery or radial artery just after its take off. This leads to the development of a Y-shaped venous system of cephalic as well as basilic vein.

Synthetic Grafts
Prosthetic AVGs are considered as secondary or tertiary access modalities to autogenous AVFs.46,47 The available graft materials can be either biological or the more commonly used synthetic ones like Dacron and PTFE grafts. They are generally created at the elbow or axilla, with a looped graft distal to the major vessels.

The major drawbacks with synthetic grafts are that they are more prone to complications and associated with higher patient morbidity and low primary and secondary patency rates, needing more interventions for salvage.48

Conclusion
The construction of a native autologous AVF on the arm or forearm is considered gold standard over prosthetic grafts and CVCs as vascular access for HD. Early referrals, thorough preoperative evaluation, careful patient and site selection, standard operative procedures, dedicated multidisciplinary team approach, and fistula care postsurgery are key factors to getting consistent results.

Author Contributions
Both the authors were involved equally in the construction, writing, editing, and review process of the manuscript of CME article on nuances of arteriovenous fistula creation for vascular access for hemodialysis.

Statement
This study was performed, and manuscript was written conforming to the Declaration of Helsinki.
