Abstract

Keywords

- ▶ Pattern Hair Loss
- ▶ Minoxidil
- ▶ Finasteride
- ▶ Post finasteride syndrome
- ▶ Dutasteride
- ▶ Topical finasteride

Pattern hair loss (PHL) is a condition that worsens with time and the only way it can be slowed down is with pharmacological intervention. Pharmacological treatments for PHL, from an evidenced-based perspective with respect to safety and efficacy, are limited to only two drugs, minoxidil and finasteride. However, there are a host of drugs being used, off-label with limited evidence. This article attempts to review the literature on this topic, and the authors add to this, with their experience of over two decades on incorporating pharmacologic treatments along with hair transplantation in their management of PHL.

Introduction

Pattern hair loss (PHL) is the most common form of hair loss seen in both genders (male pattern hair loss [MPHL] and female pattern hair loss [FPHL]). Although not a true medical disease or a threat to life, it is a cosmetic problem which technically starts at puberty and progresses with age and significantly impacts the quality of life in affected individuals.^{1–4} Man has tried to treat hair loss for centuries without a rational approach.^{5–7} Today, with internet savvy patients, most would have tried a host of remedies, online advocated treatments, over-the-counter (OTC) products, etc. With so many options available, the irony of pharmacological interventions is that to date there are only two approved drugs for PHL, both of which were not born out of a rational drug design but out of serendipity.^{3,8} Misinformation and resistance to open-ended treatment is the limiting factor in the pharmacological management of PHL.

Role of Pharmacologic Intervention in PHL

According to the authors, PHL has the following two components:

1. The existing deficit in facial aesthetics caused by hair loss (static component), which is usually addressed by hair transplantation.
2. Potential for hair loss to get worse with time (dynamic component), which is pharmacologically managed.

Both components need to be dealt with to achieve satisfactory outcome. Ensuring that the patient comprehends this along with the fact that medical management is long-term, possibly life long, is the key to successful management. Pharmacological management is necessary for all patients of PHL due to its progressive nature and that includes patients undergoing hair transplantation.^{1,3,4,9,10}

The hallmark of PHL is gradual reduction in hair shaft diameter, caused by reduced dermal papilla (DP) volume with reduced dermal papilla cells (DPCs).¹¹ The objective of pharmacological treatment in PHL is to reverse miniaturization to improve scalp coverage and prevent or slow further hair thinning and loss.

Currently, the pharmacological options with the best level of evidence from the efficacy and safety perspectives are topical minoxidil and oral finasteride for MPHL and topical minoxidil I for FPHL.^{1–4}

Table 1 Prior to starting treatment, it is essential to get a thorough blood workup mentioned in¹

Tests to be done before medical treatment of PHL
Complete blood cell count
Comprehensive metabolic panel
TSH
Iron evaluation (serum ferritin, serum iron, total iron-binding capacity)
Free and/or total testosterone and DHT
Vitamins D and B12
Additionally, in women—DHEAS and serum prolactin

Abbreviations: DHEAS, dehydroepiandrosterone sulfate; DHT, dihydrotestosterone; TSH, thyroid-stimulating hormone.

The cause of PHL is thought to be multifactorial, of which some of the elements are identified (androgens and genes) and some still under speculation (microscopic follicular inflammation, oxidative stress, prostaglandins, retinoid receptors and PPAR pathways, etc.), leaving a wide scope of therapeutic intervention. But, to date, only two molecules have been found to be helpful and safe.^{1-4,11-13}

Pretreatment Assessment

A confirmed diagnosis made on the basis of a positive family history, hair loss which is patterned (hair loss in the frontal, midscalp and crown/vertex regions with sparing of occipitoparietal region), and presence of anisotrichosis on trichoscopy are mandatory before starting treatment (→ **Table 1**).¹⁴

Hurdles in Initiating and Maintaining Patients on Pharmacological Treatment

The age group of patients consulting for hair loss varies between late teens to those in their sixties or seventies, with the majority of them being in their third or fourth decade of life.^{15,16} The younger patients are significantly distressed with the hair loss, leading to a negative body image. Moreover, most patients come armed with online information (or misinformation) and bias.^{17,18} It is one of the challenges faced by doctors to constantly counter this information and convince the patient of the right treatment protocols, albeit without any conflict of interest. To take oral or topical medications, which are not curative for the rest of their lives, is the most important limiting factor in initiating medical treatment. Patient compliance is key to success of pharmacological management of PHL. Regular periodic (every 2 or 3 months) photographic documentation of the hair loss status helps patients to objectively see the improvement in the hair loss status, which spurs them to persevere to the treatment protocol. Compliance to treatment is also facilitated by empathetic and patient counselling.

Pharmacological Management of Pattern Hair Loss

The approved drugs with labeled use in PHL, which have level 1 evidence for efficacy and safety with level A recommendation^{1,4,19,20} are as follows:

- Topical minoxidil 2% in MPHL and FPHL and 5% twice a day in MPHL and once a day in FPHL.
- Oral finasteride 1 mg in MPHL.

Off-label therapies and those with lower levels of evidence and recommendations are as follows:

- Dutasteride.
- Topical finasteride.
- Spironolactone.
- Cyproterone acetate.
- Peptides.
- Bimatoprost and latanoprost.

Minoxidil

Originally, minoxidil was an antihypertensive agent that was used largely for patients with severe and refractory hypertension. The credit for identifying its role in restoring hair goes to dermatologist Guinter Kahn who was the first to connect increased hair growth as a side effect of minoxidil usage in 1971.²¹ Topical use for PHL was formally approved in 1986 (2% for MPHL), 1993 (5% for MPHL and 2% for FPHL), in 2006 (5% foam for MPHL), and in 2014 (5% foam for FPHL).^{22,23}

How Does Minoxidil Work in PHL

PHL in men and women are the only labeled indications for topical minoxidil. Minoxidil is a piperidino-pyrimidine derivative (2,4-diamino-6 piperidino-pyrimidine-3-oxide) which works like a prodrug, needing conversion to its active metabolite—minoxidil sulfate (MS)—to exert its pharmacological actions. The active metabolite is responsible for vascular as well as the follicular actions of minoxidil.^{22,24} MS exerts its antihypertensive effect by opening of plasma membrane adenosine triphosphate (ATP)-sensitive potassium channels (KATP channels).²² The exact mechanism by which minoxidil promotes hair growth is uncertain and has been under investigation for the last few decades. Although increase in local blood flow has been suggested as a possible mechanism of hair growth, in vitro studies involving follicles in culture media have shown that minoxidil does indeed work on the KATP channels present in the hair follicle, even in the absence of any local vasculature.^{25,26} Various operating mechanisms contributing to the follicular benefits of minoxidil have been put forward. Apart from the effects on KATP channels, minoxidil causes upregulation of vascular endothelial growth factor (VEGF), which may be responsible for local angiogenesis, increased local growth factors—VEGF, hepatocyte growth factor (HGF) and insulin-like growth factor (IGF1), increased prostaglandin E2 (PGE2) production in dermal papilla fibroblasts by stimulation of prostaglandin

Fig. 1 Proposed mechanisms of action of minoxidil on hair follicles.

Fig. 2 Results of minoxidil in pattern hair loss (PHL).

endoperoxide synthase, upregulating the b-catenin pathway, decreased catagen by inhibiting TGF β-induced apoptosis of hair matrix cells, activating ERK and aKt pathways as well as activating adenosine1 and 2 receptors in DPCs; finally, it may also play a role suppressing androgen receptor (AR)-related functions (► **Fig. 1**).^{22,24–28}

Application of minoxidil causes anagen prolongation, delays catagen progression, and shortens telogen.^{22,26,29}

Fig. 3 Results of minoxidil in pattern hair loss (PHL).

Fig. 4 Results of minoxidil in pattern hair loss (PHL).

All these actions translate into improved hair growth. Shortening of telogen results in increased shedding after initiating treatment. This is seen within a week of starting minoxidil and may last a few weeks. The benefits are objectively noticeable between 6 to 12 months after starting therapy (► **Figs. 2, 3, 4**).

Pharmacokinetics of Topical Minoxidil

Direct follicular action without systemic effects justifies topical use of minoxidil³⁰ but hurdles of transdermal absorption need it to be mixed with water, ethanol and propylene glycol (PG).²⁶ PG is necessary to improve absorption but is also the cause for irritation of the skin. Limited systemic absorption (less than 99%) limits the possibility of vascular effects.³¹ Minoxidil action on the follicle is dependent on the expression of sulfotransferase enzyme in the hair follicles, which can vary in the population, and this is the reason for differential effects of minoxidil.³² The levels of this enzyme can be impacted favorably (retinoic acid) or unfavorably by certain substances (aspirin, salicylates).^{32,33}

Adverse Effects with Topical Minoxidil

Topical minoxidil is a safe drug which is evident from the fact that it is an OTC medication in many countries. But some minor adverse effects may be seen in some patients. These could be temporary and gradually reduce with time but sometimes the irritation is more severe, mandating discontinuation or modification of therapy.

The most common adverse effect which is also responsible for patients defaulting on treatment is PG-induced irritant dermatitis (contact allergy to minoxidil is rare). This can be significant in a subset of patients, mandating discontinuation of the treatment or change of formulation. The irritation is directly proportional to the minoxidil concentration (5% > 2%) ▶ **Fig. 5**.²⁶

Another reason why patients discontinue minoxidil is the initial increased hair fall caused due to shortening of telogen phase, and this should be mentioned to patients while starting minoxidil therapy, but the authors feel that this could be a pointer to its effectiveness in that patient.

Other adverse effects that may be seen are hypertrichosis, especially on the face in women. This is linked to the concentration of minoxidil (5% > 2%) or could be due to improper application.²⁶ It is always a good idea to photograph the face with the side burn and chin regions before starting treatment, so as to document any increase in facial hair with minoxidil usage ▶ **Fig. 6**.

Many patients are reluctant to use it in work or social situations, as the hair sometimes appears to be dry, dull, and stiff. This could probably be due to improper application (delivering most minoxidil onto the hair instead of the scalp), leaving precipitate of minoxidil on the hair shaft (▶ **Fig. 7**). This reluctance can be overcome by educating the patient on correct application techniques and use of conditioners and leaving on serums applied between minoxidil applications (▶ **Fig. 8a and b**).³⁴

It is extremely rare for patients to complain about hypotension, but some patients may complain about palpitations, irritation or burning of eyes, weight gain, etc.³⁵ Although it qualifies as an OTC product, topical minoxidil can have an impact on the cardiovascular system.³⁵ This may become significant in patients with cardiac compromise. Cardiologists'/physicians' opinion regarding safety of starting topical minoxidil in such patients is important. Although not com-

Fig. 8 (a) Dull look after minoxidil application. (b) Addressing dull look after minoxidil application with leave on serum.

mon, some patients do complain of headaches.²⁶ Lowering the dose helps in these cases.

How to Use Topical Minoxidil

For patients to reap benefits out of the use of topical minoxidil, they need to ensure correct application of minoxidil. It is helpful to demonstrate to the patient the correct way to apply minoxidil or direct them to videos which demonstrate the same. Minoxidil is for application to scalp, and for this, the scalp has to be dry.

Minoxidil is applied to the scalp as a liquid or foam, ideally right after bathing, so it is not washed away from towel-dried scalp (one need not blow dry it, it is okay if it is slightly damp). Maximum efficacy requires application two times daily to the affected area for men; one time daily for women (if using 5%). No other application should be made on the scalp for at least 4 hours after minoxidil application.³⁶ There is no need to massage it onto the scalp. It is important to avoid the eyes and make sure to wash hands after application.

Its off-label uses are found in the following area: alopecia areata, beard augmentation, eyebrow augmentation, post-chemotherapy hair fall and telogen effluvium,²⁶ and some have recommended for preoperative use on chest to get more follicles in anagen phase before harvesting them with follicular unit extraction (FUE).³⁷

Minoxidil Combinations and Formulations

Significant irritation caused by PG have prompted various attempts to overcome these issues by replacing PG and alcohol with alternative solvents. PG-free preparations were designed (PG-free foam) in a bid to reduce the irritation and ensure patient compliance to the treatment.^{26,38} As a personal experience, the authors have observed that the stability of locally available minoxidil foam preparations in tropical climate is not optimal and the minoxidil containers need to be refrigerated before use.

Minoxidil absorption is known to increase with the concentration of minoxidil, but studies comparing 5% minoxidil with 10% found that the former was superior to the latter in hair regrowth and caused less irritation at the same time.³⁹ The increased irritation does not justify usage of higher concentration, and the authors do not recommend usage of strengths higher than 5%.

Attempts have been made to add minoxidil with other pharmacological actives and not always successfully.⁴⁰ Tretinoin is thought to increase the absorption of minoxidil and also upregulate the expression of sulfotransferase, but studies have revealed that using a combination of minoxidil 5% + tretinoin 0.01% once a day was not superior to minoxidil 5% twice a day. This combination can cause significant irritation and may also interfere with minoxidil absorption. There is a possibility that if retinoic acid is applied a couple of hours before minoxidil application, then it may prove beneficial, but more studies are needed on the same.³⁴

Topical combination of minoxidil with finasteride is discussed in the following section.

Oral Minoxidil

The minoxidil story seems to be coming to a full circle now with studies exploring the potential use of oral minoxidil (OM) in treating hair loss. The proponents of OM have rationalized its use in this form to overcome the disadvantages of topical applications, namely, scalp irritation, daily twice application, unpredictable outcomes, etc.^{41,42} Different dosing regimens have been utilized in scarring and nonscarring alopecia, varying from 0.25 to 5 mg daily with women requiring lower doses than men.⁴² However, the studies have shown that efficacy of 1 mg OM is similar to 5% topical minoxidil. The adverse effects are seen in fair number of patients (20%) using OM, of which hypertrichosis is the most frequent (significant enough to mandate laser hair reduction).⁴³ In the authors' opinion, the risk benefit ratio of OM as compared with topical minoxidil and the fact that the available evidence for OM is not of very high quality and does not justify use of OM routinely in the management of PHL and that topical minoxidil is still the first-line therapy.^{26,43,44} More studies would be needed to elucidate safety and efficacy of OM and justify its use as the first-line therapy in PHL. As a strict off-label indication with detailed informed consent, and after proper cardiac evaluation, it could be considered in motivated young healthy adults with no comorbidities who do not tolerate topical minoxidil or see benefits in spite of proper and diligent usage.^{45,46}

Finasteride

As with minoxidil, serendipity once again played a role in identifying finasteride as a treatment for MPHL, when it was observed to promote hair growth in bald men who were taking it for benign prostate hyperplasia (BPH), leading to its approval by US Food and Drugs Administration (FDA) in 1997 for the treatment of MPHL (androgenic alopecia [AGA]).⁸

How does Finasteride Work in MPHL

What we know about androgens and MPHL

- There is increased expression of ARs, 5 α reductase type 2 enzyme (SRD5A2) and dihydrotestosterone (DHT) in the follicles of the balding regions.
- There is decrease aromatase enzyme expression in the follicles of balding scalp.
- Blocking conversion of testosterone (T) to DHT delays or prevents progress of hair loss in MPHL.⁴⁷⁻⁵²

The contributory role of androgens in FPHL is still not clear.^{52,53} The role of androgens in FPHL becomes significant if there is presence of clinical hyperandrogenism (hirsutism, weight gain, irregular menses, difficulty in conceiving) or evidence of biochemical excess of androgens. Detailed assessment to rule out hyperandrogenism is a must in patients with FPHL, which includes testosterone, free and total, DHT, dehydroepiandrosterone sulfate (DHEAS), prolactin and sex hormone-binding globulin.⁵¹

Steroid type II 5 α -reductase (SRD5A2), an intracellular enzyme present in the outer root sheath in the DP of balding follicles, converts T into DHT, which is the preferred ligand for AR.⁵⁴ DHT binding to the AR puts into motion a

cascade of events, which ultimately leads to hair follicle miniaturization.

Finasteride, a synthetic 4-azasteroid compound, is a specific and competitive inhibitor of SRD5A2, which converts T into 5 α DHT.^{55,56} Finasteride is known to reduce the scalp and serum DHT levels by 60 to 70%.^{51,54} Various studies of finasteride 1 mg orally taken daily have shown cessation of hair loss progression and improved hair growth in a significant number of patients. Finasteride usage in MPHL has shown to increase the duration of anagen with increase in hair count, improved scalp coverage, and increased hair mass.^{1,56} Finasteride does not affect T levels or binding of DHT to AR and therefore does not possess androgenic, antiandrogenic, estrogenic or antiestrogenic, or progestational or steroid hormone-related properties.^{56,57}

Pharmacokinetics

Finasteride when taken orally has a mean half-life of approximately 6 hours, mandating a daily dosage to maintain uniform blood levels. Extensive hepatic metabolism is by the cytochrome P450 enzyme system, specifically CYP3A4 enzyme subfamily. Finasteride does not have any major drug interactions^{56,58} but drugs like erythromycin or rifampicin, which impact CYP3A4 enzyme, should be used carefully with finasteride, and the authors recommend evaluation of liver function before starting treatment.⁵⁷ Finasteride is recommended in the dosage of 1 mg daily for treatment of MPHL. Although various dosages ranging from 0.01 mg to 5 mg/day have been tried, 1 mg dosage has been found to be optimal.⁵⁷

Finasteride has level 1 evidence for efficacy to prevent progression and improve hair loss in MPHL.^{1,4,19,20,32,54,56-59} Studies have revealed that the hair count and weight start show increase by approximately 6 months and the improvement continues at least for up to 5 years.^{20,57} Treatment started earlier in the course of hair loss always responds better (→Figs. 9, 10, 11).

The authors have routinely used a combination of topical minoxidil and oral finasteride as an adjunct to hair transplant surgery to tackle the dynamic and static aspects of MPHL. When used preoperatively (at least 12–16 weeks), it helps to improve yield by prolonging anagen and also helps to reduce postoperative telogen effluvium. When used postoperatively, medications help to improve the vellus hair present

Fig. 9 Results of using topical minoxidil and oral finasteride.

Fig. 10 Results of using topical minoxidil and oral finasteride.

Fig. 11 Results of using topical minoxidil and oral finasteride.

in the transplanted and surrounding areas. Improvement of these hairs not only stabilizes hair loss progression but also augments hair transplant outcomes. This approach goes a long way in optimizing donor supply over patient's lifetime and increasing the interval between two transplants.^{9,10,60,61} When planning a transplant, it is important to put these considerations across to the patient and emphasize the benefits of a holistic approach (→Fig. 12).

Adverse Effects of Oral Finasteride

Finasteride has been widely used since 1992 for BPH and 1997 for MPHL, and millions of patients having used it and benefitted from it since then. This is a reflection of its safety and efficacy. However, the controversy surrounding the adverse effects continues, confounding the doctors as well as patients about its role in therapy.

The adverse effects related to finasteride usage can be divided into sexual (reduced libido, erectile dysfunction [ED], ejaculatory problems) and nonsexual (breast tenderness and enlargement; depression; hypersensitivity reactions including rash, pruritus, urticaria, and swelling of the lips and face; and testicular pain).

The widespread information or misinformation on the Internet regarding the potential adverse effects of finasteride, along with the fact that United States National Institutes of Health added a link for postfinasteride syndrome to its Genetic and Rare Disease Information Centre,⁶² has created a

Results showing improved scalp coverage after combining hair transplantation for frontal and mid-scalp with medications addressing the thinning in the vertex region

Fig. 12 Showing beneficial effects of oral finasteride and topical minoxidil in hair transplant outcomes.

bias in the minds of patients as well as doctors who are very reluctant to use this medication.

The incidence of sexual adverse effects with SRD5A inhibitors quoted in literature range from 0.9 to 38%.⁶² Of the sexual adverse effects, ED is more common than ejaculatory dysfunction and loss of libido.^{1,62} Literature on adverse effects of finasteride includes different doses, different drugs (finasteride and dutasteride) with different indications (BPH and MPHL), and different age groups. There are some publications which link finasteride usage with sexual adverse effects⁶²⁻⁶⁷ and others which state that the association is not significant or does not exist.⁶⁸⁻⁷³ More importantly, meta-analysis of data regarding finasteride adverse effects in MPHL is not associated with statistically significant incidence.⁶⁸⁻⁷⁰ This could be probably due to the lower dosage used and the younger study population.

ED has two components—organic (levels of androgens and normal anatomy of genitals) and psychogenic, and both of these components may have an intricate relationship.⁷⁰ Finasteride lowers serum DHT without altering T levels which, due to its humoral endocrine and local paracrine effects, is more relevant or critical to maintaining erectile function than the locally acting DHT.^{68,74} Most studies emphasize the importance of T in erectile physiology, which is highlighted by the fact that patients with congenital deficiency of SRD5A have normal erectile physiology.^{68,74,75} On a subjective level, patients answering the International Index of Erectile Function questionnaire showed no difference in scores before and 6 months after starting finasteride 1 mg.^{76,77} Another factor is that hair loss may itself cause depression, lead to sexual problems, and confound the occurrence of ED.

From a psychogenic perspective, one possible explanation for the sexual adverse effects could be the “nocebo effect,” which is not directly related to the specific pharmacological effect of the drug, but due to the information about the drug being given during counselling (especially sexual side effects

with finasteride).^{62,73} The art of counselling is to develop innovative ways to reduce nocebo effects without withholding information or scaring the patient.⁷⁸ In practice, the authors navigate this difficult issue by sharing patient experiences and emphasizing the positive outcomes of finasteride with before and after pictures, downplaying the expectations of adverse effects (without distorting facts), being empathetic to the patient’s situation and, most importantly, answering all their queries patiently. An effort is made to get the history regarding any existing sexual or psychiatric problems faced by them. If the patient has history of any sexual problems or psychological issues, starting finasteride is avoided or deferred.

Another adverse issue linked to finasteride is depression. Over the years, increased usage and subsequent postmarketing feedback have been responsible for adding depression to the list of adverse symptoms in the package insert of finasteride.⁶² SRD5A enzyme is not only responsible for reduction of T to DHT but also progesterone and deoxycorticosterone to dihydroprogesterone (DHP) and dihydrodeoxycorticosterone (DHDHC), respectively. 3 α reduction converts DHT, DHP and DHDHC to steroid metabolites, which act on the gamma-aminobutyric acid (GABA) A receptors. The hypothesis for the cause of depressive symptoms occurring with finasteride therapy is linked to reduced levels neuroactive steroids, caused by SRD5A inhibition. Levels of neuroactive steroids have been found to be inversely proportional to various psychiatric conditions including depression.⁷⁹ Animal studies have yielded evidence which supports the fact that finasteride is a depressogenic drug, but human studies have not corroborated the same. This could be due to species difference in finasteride activity or the accuracy of the modalities used to assess depression-like symptoms in animals.⁷⁹ Recent publications however have found the risk of developing depression after finasteride therapy to be low and not statistically significant.^{80,81} However, more studies would be needed to validate these findings and till then it

would be a good practice to rule out any preexisting psychiatric issues in the patient and also consider and discuss the possible sexual side effects and risk of depression with patients prior to starting finasteride therapy.⁶⁵

Finasteride and Prostate Cancer

The Prostate Cancer Prevention Trial (PCPT) results showed that finasteride users were 25% less likely to develop cancer of the prostate. But the controversial finding was that the incidence of high-grade cancers was 0.7% in finasteride users.^{82,83} In view of these findings, the FDA subsequently in 2011 issued a safety warning of developing high-grade cancer as an adverse effect of finasteride.⁸³ Various studies conducted later as well as further analysis of the PCPT outcomes by factoring in the biases and accounting for PSA (increased sensitivity), showed that finasteride usage is not linked to increased incidence of high-grade prostate cancers.^{83–86}

Prostate-specific antigen (PSA) is an important tumor marker for prostate cancer, and finasteride is known to decrease the levels. There have been various recommendations about interpreting PSA levels in patients taking finasteride. As the levels are known to decrease, a compensatory adjustment of the PSA concentration (to multiply the value by two) is recommended to get the corrected value.^{87,88} However, this correction is not valid for long-term management, and any increase above the baseline is to be viewed with suspicion even if it is in normal range.⁸⁹ The authors routinely advise PSA estimation in all male patients above the age of 45 years who are agreeable to start with finasteride. The test is then repeated after 6 months of therapy and then annually. The 6-month value is taken as the new baseline and any change in that value, even if it is in the normal range, is taken seriously and further investigations advised.

Finasteride and Male Breast Cancer

A report published by Medicines and Health care products Regulatory Agency (MHRA), United Kingdom, in 2009 mentioned the occurrence of male breast cancer (MBC) in patients who received finasteride.⁹⁰ Another study in 2018 also suggested possible association between finasteride use and MBC but added that this could also be attributed to the increased surveillance and the way data was collected (ascertainment bias), which could confuse the inference.⁹¹ In 2019, a large case-control study using individual-level registry data from Denmark, Finland, and Sweden, which adjusted for confounding factors, showed that there is no association between finasteride usage and MBC.⁹²

Finasteride and Fertility

A randomized, double-blind placebo-controlled study, which reviewed the effect of 1 mg finasteride on fertility in young men, showed no significant effects on sperm concentration, total sperm per ejaculate, sperm motility, or morphology.^{58,93,94}

However, a similar study using 5 mg dose did show a statistically significant reduction in sperm count, sperm

motility, semen volume, and sperm concentration from baseline but no change in sperm morphology. These changes however were not statistically significant at 52 weeks. Moreover, these changes reverted to baseline after discontinuing treatment.⁷⁴ Another study conducted in the male infertility population showed improved semen parameters, including increased sperm count after discontinuation of finasteride.⁹⁵ This probably indicates that finasteride may not significantly impact sperm parameters, but in patients with conditions related to infertility, an amplification of the negative influence of finasteride could occur.⁹⁶ Keeping this in mind, the authors defer finasteride therapy in young men who are planning to start their family, especially if the couple is having difficulty in conceiving.

Postfinasteride Syndrome

Postfinasteride syndrome (PFS) is a collection of adverse effects causing sexual, neuropsychiatric, and physical symptoms which develop with use of finasteride for MPHL or BPH and which persist after discontinuation of treatment.^{97–99} Majority of the studies which reported on PFS were found to be of low quality, having come from doctors who are not treating hair loss, and most of them suffered from a strong selection bias and placebo effect.¹⁰⁰ Although most individuals who suffer from PFS have homogenous symptoms, the medical community is still not recognizing this as a medical condition, as most reports cannot deny nor confirm its existence as a nosological entity.^{98,101} Nevertheless, it has been added to the Genetic and Rare Disease Information Centre by the United States National Institutes of Health.⁶² One of the studies has labeled PFS as a delusional disorder of the somatic type, in a person with probably a personality disorder, with the potential of a mass psychogenic illness due to its media coverage.¹⁰¹ Most observations pertaining to PFS are mainly based on self-reporting of symptoms by the patients, and limited medical studies have not been able to identify molecular mechanisms and/or genetic determinants underlying these adverse effects.⁹⁹ The authors have not seen a single case of persistent adverse effects with finasteride therapy in a practice over two decades, but they make it a point to watch out for the red flags like a history of preexisting psychological problems such as depression or personality disorders before choosing to start with finasteride therapy.

Topical Finasteride

Although oral finasteride is approved for treatment of MPHL due to the incidence of small but significant number of adverse effects and reluctance of patients to use oral finasteride; topical finasteride was explored as an alternative. Topical finasteride is an off-label use of finasteride for MPHL. In India, it is available as a combination 0.1% finasteride with minoxidil 5%.^{102,103} The study by Casserini et al compared pharmacokinetics of topically applied finasteride with the standard oral finasteride 1 mg. The plasma DHT suppression was almost the same with topical and oral forms of finasteride, but at the same time, the maximum plasma concentration (C_{max}) of finasteride was much

Fig. 13 Improved scalp coverage with topical finasteride and minoxidil.

Fig. 14 Improved scalp coverage with topical finasteride and minoxidil.

lower with topical finasteride.¹⁰⁴ So, in effect an equal therapeutic benefit was achieved without increasing the systemic exposure to finasteride; therefore, potentially minimizing the incidence of adverse effects. The benefits in terms of hair growth are comparable to oral finasteride (→Figs. 13, 14, 15).^{102,103,105}

Dutasteride

Dutasteride, a potent type I and type II 5- α reductase inhibitor, and the logic of using this is that dual 5 α -reductase inhibition could result in greater efficacy than is observed in selective type 2 inhibition, and this dual inhibition could prevent type 1-mediated synthesis of DHT¹⁰⁶ It is approved for BPH but is also prescribed as an off-label treatment for pattern hair loss.^{1,107} It has a high level of evidence for safety and efficacy, as per the Japanese guidelines.²⁰ It is thought to

be more potent than finasteride, as it can decrease serum DHT by more than 90%, while finasteride decreases serum DHT by 70%.⁵⁴ Different studies compared dutasteride versus finasteride to assess its efficacy and safety. It has been found that dutasteride is slightly more efficacious than finasteride and the adverse effect profile is better than finasteride.^{107,108} The dosage used is 0.5 mg daily. As dutasteride has a much longer half-life and there is limited data of long-term safety, the authors do not use it as a first-line treatment in MPH. The authors offer it as an off-label drug to patients who have plateaued in their response to finasteride or have not responded to finasteride only after proper counselling.

Antiandrogens

FPHL with evidence of clinical or biochemical androgen excess would be suitable for antiandrogen therapy as compared with or without any evidence of hyperandrogenism.¹⁹ Hormonal treatment for FPHL can be divided into two broad groups, antiandrogens and estrogenic (or antiestrogenic) drugs.⁴ Two commonly used drugs are cyproterone acetate and spironolactone, although evidence of efficacy for any of these treatments is limited.⁵⁴

Spironolactone

It is by far the most common antiandrogen used off-label in FPHL.^{1,4} Spironolactone is a potassium-sparing diuretic, structurally related to aldosterone (antagonist), which acts as an antiandrogenic by competitively inhibiting the androgen receptor in target tissues and also inhibits ovarian production of androgens, reducing the levels of total T and competitively blocking the AR.^{1,4,54} The dosage ranges from 50 mg/day to 200 mg/day for at least 6 months. Some patients may face adverse effects like postural hypotension and electrolyte imbalance.⁴ It is contraindicated in MPH.

Cyproterone Acetate

Cyproterone acetate (CA) is an AR blocker and potent progesterone derivative that prevents dihydroxytestosterone from binding to the AR and inhibits release of follicle-stimulating hormone (FSH) and luteinizing hormone (LH), thereby reducing testosterone levels.^{1,4,54} CA is not approved in the United States. It is available combined with ethinyl estradiol as an oral contraceptive in many countries (2 mg CA with ethinyl estradiol 0.035 mg) and started on day 1 of the menses for 21 days, followed by a break of 7 days. Studies have shown statistically significant improvement in hair

Fig. 15 Improvement with minoxidil and later with minoxidil and finasteride combination

growth as compared with placebo.⁴ It is important to keep a track of liver function, as it can cause liver toxicity. The authors have used it in patients of FPHL who also have polycystic ovarian disease (PCOD).

Prostaglandin Analogues

The beneficial effects of prostaglandin analogue on hair growth were noted when eyelashes improved with topical use for treatment of glaucoma. PGD2 levels are associated with miniaturization in balding scalp while levels of PGE2 and PGF2 are reduced.⁵⁹ PGF2 analogues bimatoprost and latanoprost are known to promote hair growth. But currently there is insufficient evidence to use them in PHL.^{4,20}

Ketoconazole

Ketoconazole is an antifungal agent available as a shampoo in combination with zinc pyrithione. It is thought to have local DHT-blocking effects as well as an anti-inflammatory effect.^{1,4,20} Furthermore, change in the microbiome of the hair follicle, causing microinflammation in the perifollicular region, is thought to be one of the factors implicated in PHL.^{1,59} Use of ketoconazole with its antifungal properties and anti-inflammatory properties of zinc pyrithione has worked well in conjunction with topical minoxidil.⁵⁹ A few noncontrolled studies have shown benefits in MPHL as well as in FPHL with androgen excess.^{1,4,20,59}

Saw Palmetto (*Serenoa repens*)

Saw palmetto (SP), a botanical extract from the berries of *Serenoa repens*, is one among the many naturally occurring SRD5A inhibitors which has gained popularity as a magical remedy for MPHL.^{59,109,110} Very few studies of efficacy of SP in PHL exist and most of the data on SP is from studies of its use in BPH.¹¹⁰ It is listed in US Pharmacopeia under food supplements and available as dried berries or tablets of the extract. The dosage is 160 mg twice a day.¹⁰⁹ In absence of strong evidence of efficacy, it cannot be recommended.

Other botanicals which have been proposed to be used in PHL are green tea (*C sinensis*), pumpkin seed (*C pepo*), rosemary (*Rosmarinus officinalis*), grape seed (*Vitis vinifera*), and licorice (*G glabra*). These do not have supporting data to recommend their use in PHL.

Peptides

Botanical extracts have been used to treat PHL, especially biomimetic peptides such as acetyltetrapeptide-1 and 3, which are combined with an isoflavone derived from red clover (biochanin-A). There is very little literature support, and their role in management of PHL is not significant. Probably, they may play a role of placebo.

Nutritional Supplements

The hair follicle is a miniature organ with a high cellular turnover and a high metabolic rate, which mandates a constant supply of energy and nutrients. So, obviously nutrient deficiencies will impact structure and growth of hair.^{111,112} The kind of hair loss seen with nutrient deficiencies is generally of a diffuse variety and does not have

the typical characteristics of pattern hair loss. Nutrient supplementation has been used empirically to address hair loss concerns, with many patients using OTC products to manage hair loss.¹¹¹⁻¹¹³ However, the role of nutrient deficiencies in causation of pattern hair loss has never been really verified.¹¹² However, in patients of pattern hair loss who have coexisting deficiencies of certain nutrients like vitamin D or iron, supplementing these can improve the outcomes in pattern hair loss.¹¹³ Data on the role of nutrient supplementation in the absence of deficiency is extremely limited.¹¹²

Summary

The goal of the pharmacological management of PHL is to prevent further progression of hair loss and promote hair regrowth and improve scalp coverage. The key to successfully management of PHL using medications is proper diagnosis, adequate patient counselling, regular periodic follow-up, watching for adverse issues, and constant reassurance to the patient. The success of the treatment is to a large extent controlled by patient compliance and ensuring this is important. Emphasizing the following points is critical for its success:

1. That PHL is a condition that is going to progress with time and medical management would be necessary either alone or in conjunction with hair transplantation.
2. It is critical to give the patient all options of dealing with his or her hair loss, explaining the pros and cons of each approach. With all the options advertised on the Internet and social media, patients tend to be overwhelmed and confused. Patience and empathy along with clear recommendations are helpful to the patient, especially young men who are in denial and do not accept medical therapy and would rather proceed with hair transplantation.
3. It is important to mention the benefits and the adverse effects without highlighting them; periodic photographic documentation of the progress is crucial and always helps the patient to stay on track with the treatment. Important to point out that majority of the patients do not encounter adverse effects.
4. Medical therapy is best started early, used daily, and continued for life.
5. Currently, there are only two approved medications to achieve this along with off-label uses of other medications, but in terms of efficacy and safety, only topical minoxidil and oral finasteride in MPHL and topical minoxidil for FPHL have the evidence to support their use.
6. However, it is important to wait for at least 6 months before expecting and visible change. It is ideal to combine minoxidil and finasteride in MPHL as they work synergistically.
7. Pharmacotherapy plays an important role in the hair transplant setting. Use of medications perioperatively helps to optimize the amount of donor harvest and at the same time augments the results of the transplant, thereby conserving the donor area for future needs.

8. Initial hair fall occurring with treatment should not be a cause of worry and usually settles in 8 to 10 weeks. It is always helpful to educate the patient on the proper technique of minoxidil application.
9. Cosmetic management for dealing with dry and dull hair after minoxidil application must be shown to the patient.
10. Sexual side effects after oral finasteride therapy, if they do occur, are usually seen after at least 6 months of therapy. It is important to reassure the patient. If they are not severe, it is okay to continue with the finasteride after counselling or may be discontinued with the understanding that the hair loss will return to pretreatment stage. There is also the option of using topical finasteride with minoxidil in apprehensive patients.
