Abstract
Herbal medicine has been used to treat diseases for centuries; however, the biological active components and the mechanistic understanding of actions of plant-derived drugs are permanently discussed. MicroRNAs are a class of small, non-coding RNAs that play crucial roles as regulators of gene expression. In recent years, an increasing number of reports showed that microRNAs not only execute biological functions within their original system, they can also be transmitted from one species to another, inducing a posttranscriptional repression of protein synthesis in the recipient. This cross-kingdom regulation of microRNAs provides thrilling clues that small RNAs from medicinal plants might act as new bioactive components, interacting with the mammalian system.

In this article, we provide an overview of the cross-kingdom communication of plant-derived microRNAs. We summarize the microRNAs identified in medicinal plants, their potential targets in mammals, and discuss several recent studies concerning the therapeutic applications of plant-based microRNAs. Health regulations of herbal microRNAs in mammals are a new concept. Continuing efforts in this area will broaden our understanding of biological actions of herbal remedies, and will open the way for the development of new approaches to prevent or treat human diseases.

Introduction
Endogenous microRNAs (miRNAs) are a class of single-stranded non-coding RNA molecules of approximately 22 nucleotides that play crucial roles in gene expression [1]. They generally bind to complimentary sequences in the 3′ untranslated region (UTR) of specific protein-coding genes, but can also interact with other regions of the gene including 5′ UTR and the coding region, inducing mRNA cleavage or translational repression [2]. miRNAs are highly pleiotropic and a single miRNA can recognize hundreds of mRNA transcripts, allowing them to regulate a diverse range of biological pathways. In mammals, an estimated 60% of all protein-coding genes may contain miRNA binding sites [3, 4]. Furthermore, miRNA dysregulation is frequently associated with human diseases such as cancer, cardiovascular diseases, central nervous system diseases, and metabolic disorders [5–8], suggesting their potential as targets for the development of novel therapies for several diseases. There are currently many efforts focusing on the development of miRNA therapeutics for the treatment of human diseases. Several preclinical studies on therapeutic miRNA replacement have been initiated [9–11], and the first liposomal nanoparticle formulation of miR-34a mimic (MRX34) has entered clinical trials in patients with primary liver cancer [12], highlighting the therapeutic potential of miRNA-based novel approaches to treat diseases. However, severe on-target or off-target side effects could be caused by artificial miRNAs [13, 14].

Herbal medicine has been used to treat diseases for centuries. Bioactive secondary metabolites such as polyphenols, alkaloids, saponins, and tannins have been systematically studied and used as an important source for drugs. However, synthetic supplements of phytochemicals often do not have the same efficacy as complex herb materials. The natural biological active components and mechanistic understanding of actions of plant-derived drugs are permanently discussed.

Herbal remedies may produce a beneficial effect by regulating mammalian miRNA expressions. Medicinal plant extracts and secondary metabolites such as Dioscorea opposita Thunb. (Dioscoreaceae) extract, ginsenoside Rh2, berberine, and waltonitone were reported to modulate disease-associated miRNA levels [15–18]. Notably, oral consumption of a plant-based diet may lead to the cross-kingdom transfer of plant-derived miRNAs in mammals. Zhang et al. [19] reported miRNAs derived from plant-based foods function as active signalling molecules to regulate mammalian genes. The authors showed that exogenous miRNAs (e.g., MIR168a and MIR156a) from rice were absorbed by cells of the gastrointestinal (GI) tract of the consuming animal, packaged into exosomes, then migrated through the plasma, and were delivered to specific organs where they bound to low-density lipoprotein receptor adapter protein 1 (LDLRAP1) mRNA and inhibited LDLRAP1 expression, thereby influencing cholesterol transport [19]. These studies provide thrilling clues that miRNAs might act as new bioactive compounds in medicinal plants. If this hypothesis can be validated, it will broaden our understanding of herbal remedies and, more importantly, will provide new insights into the development of miRNA-based therapeutics with high efficiency, reduced side effects, and low costs. This review provides current knowledge of cross-kingdom communication of plant-derived miRNAs, summarizes the miRNAs identified in medicinal plants, and discusses several recent studies concerning the therapeutic applications of medicinal plant-based miRNAs.

Evidence for the Uptake of Plant miRNAs by Mammals

Immediately after Zhang’s group discovery, numerous details of this study have been appraised. In general, follow-up studies have focused on detecting exogenous small RNAs in mammals after different diets. The results remain controversial, as summarized in Table 1, with some findings being consistent with the original publication [19–27] while others are questioning the results [28–32].

Recent reports from two groups have attracted great attention. Yang et al. [20] identified the influence of diet preference and health issues on the uptake of plant-based small RNAs. A significant increase of plant miRNA MIR2911 in both blood and urine was observed in mice that were fed with an herbal diet (Lonicerajaponica Thunb., Caprifoliaceae; common name: honeysuckle) for several days. Damaged guts resulting from chemotherapeutic (cisplatin) treatment also enhanced plant-based miRNA uptake. In addition, a single large oral dose of exogenous miRNAs (e.g., 400 pmol of synthetic MIR2911 or MIR168a) facilitated only the short-term detection of serum miRNAs. The following study demonstrated that the level of circulating MIR2911 was associated with the dietary intake level [33]. Zhang’s group raised the critical issues for the accurate measurement of exogenous miRNAs such as RNA extraction method and internal controls [21]. These studies supply reasonable explanations on the publications reporting undetectable exogenous miRNAs. Firstly, small dosages over short time feedings of a plant diet may not induce detectable miRNAs in plasma. Secondly, natural ingredients in an herbal diet may protect plant miRNAs against degradation and enhance the uptake of miRNAs in the mammalian system, while naked miRNAs may not survive the digestion and circulation process. Thirdly, the health conditions of the GI tract may influence the uptake of plant-based miRNAs. Fourthly, not only the plant miRNAs in plasma, but the potential deposition of dietary miRNAs in other body tissues should also be taken into account. Finally, canonical methods for exogenous plant miRNA measurement are necessary to ensure the sensitivity and precision of miRNA detection.

Plant-Based miRNAs for Therapeutics

Although the role of exogenous miRNAs is currently not well understood, the biological effects of plant miRNA in the mammalian system have been profiled. Using computational tools, 12 putative miRNAs were identified from Curcuma longa L. (Zingiberaceae) and found to bind with various target genes related to human diseases such as diabetes mellitus type II, cardiovascular disorders, Alzheimer’s, cancer, and thalassemia [34]. Similarly, a total of six putative miRNAs were identified from Gmelina arborea Roxb. (Lamiaceae), while the mammalian target genes associated with cancer, blood borne disease, and other urinary infections were predicted [35].

Exosomes are one of the natural carriers of miRNA, serving as mediators in extracellular communication [36]. Using grape exosome-like nanoparticles (GELNs) as models, the biological impacts of plant exosomes have been investigated. GELNs can penetrate through the intestinal barrier, can be taken up by intestinal stem cells, and mediate intestinal tissue remodelling [37]. Oral administration of GELNs protected mice against dextran sulfate sodium-induced colitis. Apart from proteins and lipids, miRNAs, with almost 100 different kinds, were identified from GELNs [37]. Furthermore, exosome-like nanoparticles derived from edible plants, including grapes, grapefruit, ginger, and carrots, were taken up by mouse intestinal macrophages and stem cells. They were biologically active in maintaining intestinal homeostasis through activation of nuclear factor (erythroid-derived 2)-like-2 factor (Nrf-2), induction of anti-inflammatory molecules, and activation of Wnt signalling in recipient cells [38]. These studies suggested that plant miRNAs might be packaged into exosome-like nanoparticles that would be taken up by the intestine, and exert beneficial effects under both physiological and pathological conditions.

The most direct evidence of therapeutic effects of plant miRNAs has been recently published by Zhang’s group [22]. A plant-derived miRNA, MIR2911, is highly stable in the decoction of a Chinese herb honeysuckle, which has been traditionally used in China for centuries to treat influenza infection. This miRNA can be absorbed by the GI tract and be delivered via the bloodstream to the lungs of the animals, which were continuously fed with a honeysuckle decoction. Importantly, this plant miRNA could directly target various influenza A viruses, suppress their replication process, and protect against influenza virus infections in mice. The region of the influenza genome that MIR2911 targeted was also identified, and validated in a mutant virus in which the sequence was modified and resistant to MIR2911 treatment [22]. This groundbreaking study suggested that plant miRNA may act as a novel bioactive ingredient that can be absorbed by mammals and reduce the risk of many diseases.

Recently, the therapeutic potential of plant-based miRNAs in cancer was experimentally confirmed [23]. A cocktail of three mammalian tumor suppressor miRNAs was synthesized with methyl groups on the 2′ position of the ribose of the 3′ nucleotide to mimic miRNAs of plant origin. Oral administration of these plant-based tumor suppressor miRNAs together with total plant RNA [isolated from Arbidopsis thaliana (L.) Heynh (Brassica-

HTS: high-throughput sequencing; qRT-PCR: quantitative reverse transcriptase polymerase chain reaction
miRNA has been further confirmed using in vitro and in vivo models [24]. Plant-derived miR159, presented in both raw and cooked foods (e.g., broccoli), was not only abundant in healthy human serum, but also detectable in breast cancer tissues. By targeting 3′UTR of transcription factor 7 (TCF7), both synthetic 2-O-methylated miR159 and human serum extracellular vesicles (EVs) significantly suppressed breast cancer cell proliferation. In tumor xenograft models, the mice that were continuously fed with synthetic miR159 showed significantly reduced tumor growth compared with those that received scrambled control oligonucleotides. However, no affection was observed in the xenograft tumors that stably overexpressed TCF7 without the 3′UTR [24]. This study consolidated the assumption that circulating miRNAs absorbed from dietary plants can be transported through EVs-mediated trafficking, reach target tissue, and impact human health and disease.

It is noteworthy that reaching biologically active levels of circulating plant miRNAs through oral intake might require feeding with an herbal decoction, ground plant material, or food matrix [19,22,37] together, or long-term feeding regimes [22–24], suggesting that a plant-derived matrix as well as prolonged exposure might be the important factors that facilitate the high level uptake of plant miRNAs with therapeutic effects.

**Stability of Plant miRNAs**

A crucial concern regarding therapeutic plant miRNAs is their stability in the preparation process as well as in mammalian circulation. The innate capacity of plant-derived miRNAs (e.g., miR166, miR167, miR168, and miR159) are degradation resistant, as evidenced that storage, processing, and cooking do not abolish the plant miRNAs present in rice, soybeans, potatoes, broccoli, and cabbage [19,24,39]. Unlike mRNA that losses integrity during processing, plant miRNAs are robust during soaking, boiling, and homogenization processes, and even survive under unfavorable physiological conditions such as an extreme pH (e.g., simulated gastric fluid with pH of 1.2), frequent bowel movements, and potent ribonuclease (RNase) treatment [19,39]. However, it is also reported that the majority of miRNAs were degraded in the honesuckle decocation after boiling for 30 min, while MIR2911 possesses a specific sequence and high GC content, which makes it highly stable in this decocotion and resistant to RNase treatment [22]. These observations suggested that some plant-based miRNAs are in a stable form that can withstand not only the preparation process, but also the digestion and circulation process, ensuring their regulatory activity.

Several mechanisms regarding the stability of plant miRNAs have been suggested:

1. 2′-O-Methylation in plant miRNAs enhances their stability by protecting them from exonucleolytic digestion and uridylation [40,41];
2. Stabilization of circulating miRNAs is associated with RNA-binding proteins such as Argonaute proteins (AGOs) [42–44] and nucleophosmin 1 [45];
3. miRNA carriers such as exosomes, microvesicles, and high-density lipoprotein protect miRNAs from degradation [38,46,47];
4. The unique sequence and GC content of a plant miRNA also influences its stability [22];
5. Some plant extracts and secondary metabolites such as extracts from *Phyllanthus reticulatus* Poir. (*Phyllanthaceae*), *Ananas comosus* (L.) Merr. (*Bromeliaceae*), *Aglaya anphanamixis* Pellegr. (*Meliaaceae*), green tea, and polyphenols (e.g., epigallocatechin gallate, epicatechin, epicatechin gallate, and epigallocatechin) possess potent ribonuclease inhibitory activities [48–51], which may protect plant miRNAs from the enzymatic environment of the digestive tract;
6. The lipid, proteins, or polysaccharides presented in plants may protect miRNAs or miRNA carriers from degradation during preparation and processing.

**Oral Delivery of Plant miRNAs**

Oral application is the dominant route of application for herbal preparations. Even if they are stable during preparation and digestion processes, could these exogenous miRNAs cross biological barriers? Despite increasing efforts, the mechanisms of functional transfer of plant miRNAs to cross the intestinal barrier remain unclear. Given the instability of naked RNA, it would be possible that miRNAs in plant materials are packaged into protein complexes and/or lipid vesicles and recognized by a mammalian transport system. Several mechanisms for the intestinal permeability of exogenous miRNAs have been proposed:

1. The RNA-containing complexes are internalized into the intestinal epithelia and become engulfed exosomes. Some of them may merge with endosomes and undergo transcytosis that transports macromolecules from one side to the other side of a biological barrier, while some other fused endosomes mature into lysosomes and undergo degradation [52,53];
2. The RNA carriers might be transferred through M cells in Peyer’s patches of the intestine to macrophages or and dendritic cells in the gut-associated lymphoid tissue (GALT). These GALT immune cells contribute to the subsequent distribution of RNA-containing complexes throughout the body [54,55];
3. Plant miRNAs packaged within exosome-like nanoparticles could be taken up by intestinal stem cells or macrophages where they may exert biological functions [37,38];
4. Although naked plant miRNAs are instable and may survive only for a few hours [19], it is possible that these unprotected miRNAs are uptaken into the cytoplasm by receptor-mediated endocytosis or transmembrane miRNA transporters [52–56];
5. Additionally, altered intestinal permeability resulting from GI tract diseases, stress, malnutrition as well as folk remedies may enhance the uptake of foreign miRNAs [23,55].

Considering that the uptake of plant miRNAs in mammals is not necessarily related to the abundance of miRNAs in the plants [19,24], there might exist a class of plant miRNAs or miRNA carriers with specific signatures that are recognized and preferentially taken up by the mammalian GI tract. After crossing the intestinal barrier, plant miRNAs or miRNA carriers might be repacked into microvesicles and delivered to different tissues/cells where the miRNAs modulate the expression of their target genes [19,22].
In mammalian organisms, proteins at the surface of miRNA-containing lipid vesicles take part in the target-specific internalization into cells, such as exosome surface proteins tetraspanins and lectins, while integrins, proteoglycans, and lectin receptor proteins on the surface of recipient cells may serve as receptors for the exosome uptake [57]. However, the molecules on the plant miRNA carriers responsible for the interaction with the mammalian GI tract as well as the target cells have not been elucidated. It is necessary to mention that not all the ingested miRNAs end up in the bloodstream with potential functions. The level of exogenous miRNA matters to their biological function. It is generally considered that a threshold concentration of 100 copies per cell is required for miRNAs to execute their function [22]. From the published data, although some plant-derived miRNAs (e.g., miR160 a, miR162 a, and miR390 a) are detected in human serum [19], they may not be biologically active.

**miRNAs in Medicinal Plants**

Identification of plant miRNAs is the prerequisite for the understanding of their functions. Genetic and computational approaches are usually used for the investigation of miRNAs. Based on the publicly available genome sequence or expressed sequence tags (ESTs), computational methods have been used for the prediction of evolutionary conserved plant miRNAs among different species. However, except for intensively studied herbs such as *Panax ginseng* C.A.Mey (Araliaceae), *Salvia miltiorrhiza* Bunge (Lamiaceae), *Lycium chinense* Mill. (Solanaceae), and *Cynara cardunculus* L. (Asteraceae) [58–61], limited genomic data are available for medicinal plants. With the recent advent of high-throughput sequencing (HTS) technology, characterization of miRNAs through sRNA, transcriptome, or genome sequencing has become a routine tool for miRNA research. According to our current knowledge, a total of 44 medicinal plants with identified miRNAs are available in PubMed, Science Scope, and miRase databases (Table 2). With the aid of computational approaches, the functions of plant miRNA have been predicted. They are involved in various plant biological processes, including plant growth development, signal transduction, and stress responses [62–66]. Secondary metabolites have generally been considered as the pharmacological active compounds in medicinal plants, and the role of miRNAs in regulating the production of bioactive secondary metabolites has gained high attention [67–71]. It is noteworthy that even the efficacy of some herb remedies (e.g., *Viscum album* L. (Santalaceae) or *Vitex agnus-castus* L. (Lamiaceae)) has been clinically demonstrated, though the scientifical explanation of their pharmacological activities are not convincing from the experimental data about concentration, pharmacological activity, bioavailability, and metabolism of secondary metabolites present in the used extracts. One possibility to explain this gap might be the diversification of the bioactive substances. Besides the well-known plant secondary products, miRNAs produced by the mother plant may also serve as a mediator between botanicals and health-associated processes. A few studies demonstrated the therapeutics effects of herb-derived miRNAs in mammalian diseases and infections, such as cancer and influenza [22, 24, 34, 35]. Characterization of mammalian target genes of medicinal plant miRNAs using computational and experimental approaches might be a practical way for identifying functional miRNAs. Four features are commonly used for the computational recognition of miRNA targets [72]:

1. Base-pairing between the “seed” (the first 2–8 nucleotides starting at the 5′ end and counting toward the 3′ end of a mature miRNA) and its target gene;
2. Low free energy (a negative change in overall free energy during a reaction) is expected of the authentic miRNA target pairs;
3. An optional rule for target prediction requires cross-species conservation of the putative binding sites;
4. Site accessibility is an additional rule to measure the ease with which an miRNA can locate and hybridize with an mRNA target.

Using these criteria, it is not surprising to identify the mammalian targets of herbal miRNAs, while approximately 50 human genes were identified as putative targets of MIR168 a [19]. Table 2 summarizes the currently known miRNAs from medicinal plants (more information such as traditional use/clinical importance and the main bioactive ingredients of these medicinal plants is supplied in Table S1, Supporting Information), and identification of their potential mammalian targets can be a promising starting point for their cross-kingdom regulatory effects studies. The following up of experimental evidence is required to validate computational predictions since the algorithms based on the physical properties of miRNA regulation may generate many false positive results [73]. On the other hand, bioinformatics tools with additional and more sophisticated analysis allowing more accurate identification of corresponding miRNA targets for these herbal miRNAs need to be developed.

**Conclusions and Outlook**

Secondary metabolites serve as bioactive components in medicinal plants, however, the experimental evidence is not convincing regarding their therapeutic effects. It is now documented that the eukaryotic organism of different kingdoms could exchange miRNAs as signals affecting gene expression, indicating the possibility that miRNAs act as a new bioactive component in herbal remedies. The potential of herbal medicine-derived miRNAs in regulating human health or targeting genes associated with diseases are at a very early, exploratory stage. Conclusive validation studies are urgently needed to address this issue. It is necessary to evaluate the stability of herbal miRNAs during the preparation and digestion processes, and in what forms these miRNAs existed. If and to what extent plant-derived miRNAs are absorbed by mammals needs to be investigated. Furthermore, the mechanisms of intestinal absorption, tissue recognition, bioavailability, and function of herbal miRNAs should be established. Given the secondary metabolites presented in herbal preparations, future studies will determine if and how these secondary metabolites influence the stability and uptake of exogenous miRNAs by mammals.

Health regulation by herbal miRNAs is a new concept with a wide range of putative applications, which may include artificial synthesis of therapeutic plant-derived miRNAs that might possess lower side effects, artificially loading miRNAs into plant materials to enhance their *in vivo* efficacy, and discovery of novel therapeutic target genes. Continuing pursuit in this nascent area will not only broaden our understanding of biological actions of herbal remedies, but also open the ways for the development of new approaches to prevent or treat human diseases.

<tbody>
<tr>
<td>Vaccinium corybosum L.</td>
<td>Ericaceae</td>
<td>EST-based comparative genomics approach.</td>
<td>9 potential miRNAs</td>
<td>A total of 34 target involved in transcription, RNA splicing and binding, DNA duplication, signal transduction, transport and trafficking, stress response, as well as synthesis and metabolic processes.</td>
<td>[85]</td>
</tr>
<tr>
<td>Ricinus communis L.</td>
<td>Euphorbiaceae</td>
<td>sRNA sequencing, computational prediction and experimental validation.</td>
<td>86 conserved miRNAs</td>
<td>Target genes involved in the growth and development process.</td>
<td>[86]</td>
</tr>
<tr>
<td>Hypericum perforatum L.</td>
<td>Hypericaceae</td>
<td>Computational investigation prediction and experimental validation.</td>
<td>7 pre-miRNAs</td>
<td>Targets involved in metabolism, response to stress response, flower development, and plant reproduction.</td>
<td>[87]</td>
</tr>
<tr>
<td>Pogostemon cablin Benth</td>
<td>Lamiaceae</td>
<td>Experimental validation.</td>
<td>miR 156a</td>
<td>Targets regulated terpene synthases.</td>
<td>[68]</td>
</tr>
<tr>
<td>Ocimum basilicum L.</td>
<td>Lamiaceae</td>
<td>EST-based computational prediction and experimental validation.</td>
<td>9 miRNA candidates</td>
<td>A total of 13 potential targets involved in stress response and secondary metabolite regulation.</td>
<td>[88]</td>
</tr>
<tr>
<td>Salvia miltiorrhiza Bunge</td>
<td>Lamiaceae</td>
<td>sRNA sequencing, computational prediction, and experimental validation.</td>
<td>452 known miRNAs and 40 novel miRNAs</td>
<td>A total of 69 potential targets including acetyl-CoA C-acetyltransferase and those involved in the biosynthesis of tanshinones.</td>
<td>[69]</td>
</tr>
<tr>
<td>Salvia sclarea L.</td>
<td>Lamiaceae</td>
<td>EST-based analysis and computational prediction.</td>
<td>18 conserved miRNAs</td>
<td>A total of 19 potential target genes involved in transcription, metabolism, or abiotic stress response and 2 targets with no known predicted function.</td>
<td>[89]</td>
</tr>
<tr>
<td>Linum usitatissimum L.</td>
<td>Linaceae</td>
<td>Genome-based bioinformatics analysis and experimental validation.</td>
<td>116 conserved miRNAs belonging to 23 families</td>
<td>A total of 142 putative genes involved in transcription, diverse physiological, and metabolic processes.</td>
<td>[90]</td>
</tr>
<tr>
<td>Dendrobium officinale Kimura et Migo</td>
<td>Orchidaceae</td>
<td>RNA sequencing, sRNA sequencing, and computational prediction.</td>
<td>1047 miRNA candidates</td>
<td>A total of 1257 potential targets involved in hormone signalling, plant development, hormone signalling, AGO1-related regulation, and secondary metabolism.</td>
<td>[91]</td>
</tr>
<tr>
<td>Papaver somniferum L.</td>
<td>Papaveraceae</td>
<td>sRNA sequencing, computational prediction, and experimental validation.</td>
<td>316 conserved miRNAs and 11 novel miRNAs</td>
<td>A total of 1469 target transcripts involved in stress response to stress against various factors and secondary metabolite biosynthesis processes.</td>
<td>[70]</td>
</tr>
<tr>
<td>Digitalis purpurea L.</td>
<td>Plantaginaceae</td>
<td>EST library construction and sequencing, computational prediction, and experimental validation.</td>
<td>13 miRNAs</td>
<td>Target genes involved in metabolism, RNA process, transcriptional regulation, signal transduction, and those with unknown functions.</td>
<td>[71]</td>
</tr>
<tr>
<td>Coffea arabica L.</td>
<td>Rubiaceae</td>
<td>EST-based bioinformatics analysis.</td>
<td>1 potential miRNA</td>
<td>A total of 6 potential target genes involved in biological processes such as response to chitin, cold, salt stress, and water deprivation.</td>
<td>[92]</td>
</tr>
<tr>
<td>Lydium chinense Mill.</td>
<td>Solanaceae</td>
<td>sRNA sequencing, computational prediction, and experimental validation.</td>
<td>60 conserved miRNAs belonging to 31 families and 30 putative novel miRNAs</td>
<td>Potential targets were involved in a wide range of metabolic and regulatory pathways including fruit maturation, lycopene biosynthesis, and signalling pathways.</td>
<td>[60]</td>
</tr>
<tr>
<td>Picrorhiza kurroa Royle ex Benth</td>
<td>Scrophulariaceae</td>
<td>Transcriptome sequencing, computational prediction, and experimental validation.</td>
<td>18 conserved miRNAs</td>
<td>A total of 30 potential targets involved in signal transduction, nucleic acid metabolism, disease resistance, hormonal regulation, developmental processes, and secondary metabolism.</td>
<td>[93]</td>
</tr>
<tr>
<td>Rehmannia glutinosa Libosch</td>
<td>Scrophulariaceae</td>
<td>Transcriptome sequencing, sRNA sequencing, computational prediction, and experimental validation.</td>
<td>589 conserved miRNAs and 6 novel miRNAsfamilies</td>
<td>A total of 165 transcript targets involved in biological regulation, response to stimuli, development, and metabolic processes.</td>
<td>[94]</td>
</tr>
<tr>
<td>Taxus chinensis var. mairei</td>
<td>Taxaceae</td>
<td>sRNA sequencing, computational prediction, and experimental validation.</td>
<td>871 mature miRNA and 869 mRNA precursors</td>
<td>The functions of the putative target genes are largely unknown, implying that the novel miRNAs are involved in the Taxus-specific biological processes.</td>
<td>[95]</td>
</tr>
<tr>
<td>Cornelio sinensis (L.) O. Kuntze</td>
<td>Theaceae</td>
<td>Bioinformatics analysis.</td>
<td>miRNAs candidates</td>
<td>A total of 30 potential target genes involved in transcription, physiological processes, and those with hypothetical or unknown functions.</td>
<td>[96]</td>
</tr>
<tr>
<td>Aquilaria sinensis (Lour.) Gilg.</td>
<td>Thymelaeaceae</td>
<td>sRNA sequencing, computational prediction, and experimental validation.</td>
<td>27 novel miRNAs and 74 putative conserved miRNAs</td>
<td>Targets involved in stress response and agarwood formation.</td>
<td>[97]</td>
</tr>

## Supporting information

A table displaying the traditional use or clinical importance and the main bioactive ingredients of medicinal plants with currently known miRNAs is available as Supporting Information.

## Acknowledgments

This work was financially supported by the FUB – CSC Postdoctoral Research Program (2011506300001) of the China Scholarship Council (CSC) and Freie Universität Berlin (FUB).

## Conflict of Interest

The authors declare that there are no conflicts of interest.
