A 53-year-old man with chronic pancreatitis presented with abdominal pain and sepsis. Imaging revealed a liver abscess secondary to distal biliary obstruction. Following drainage of his abscess, the patient underwent endoscopic retrograde cholangiopancreatography (ERCP) with placement of a fully covered metal biliary stent across a 2-cm suspicious shouldered and irregular low common bile duct stricture. A pancreatic head malignancy was suspected at ERCP and on computed tomography (CT) imaging. The regional specialist hepatobiliary multidisciplinary team (MDT) recommended endoscopic ultrasound with fine needle aspiration (EUS-FNA). EUS-FNA was difficult because of the changes of severe chronic calcific pancreatitis, duodenal stenosis, increased pancreatic head vascularity, and metal stent artefact. Five needle passes were made with a 22-gauge needle (Boston Scientific, Marlborough, Massachusetts, USA) using standard technique. Cytology was consistent with pancreatitis, with no evidence of malignancy.

A routine chest radiograph 6 months later revealed a new linear density in the heart (Fig. 1). The interim abdominal CT imaging was re-reviewed (Fig. 2). Although not recognized at the time, owing to the highly calcified pancreas, it became clear that a fractured EUS-needle tip had migrated from the duodenal wall into the epigastrium (Fig. 3), then through the diaphragm and into the left ventricle. On a subsequent chest radiograph, the needle had disappeared and a further CT scan revealed that it had migrated to the aortic bifurcation (Fig. 4a).

The needle was retrieved endovascularly via bilateral common femoral artery access. It was first snared from above with a protective occlusion balloon placed below in the left iliac artery (Fig. 4b). The balloon was deflated, the needle was snared from below and was then removed through the left groin sheath (Video 1). The patient made an uneventful recovery after the procedure.

Endoscopic needle fracture has been previously described in the upper gastrointestinal tract [1, 2] and in a bronchoscopy setting [3]. Fractured metal sharps such as orthopedic fixation wires have been known to migrate into the arterial circulation, including into the heart [4].

This is the first known case of an endoscopic needle migrating intra-arterially.
